Abstract

In this paper we shall report on our progress using spatial constraint system as an abstract representation of modal and epistemic behaviour. First we shall give an introduction as well as the background to our work. Then, we present our preliminary results on the representation of modal behaviour by using spatial constraint systems. Then, we present our ongoing work on the characterization of the epistemic notion of knowledge. Finally, we discuss about the future work of our research.

1 Introduction

Epistemic, mobile and spatial behaviour are common practice in today’s distributed systems. The intrinsic epistemic nature of these systems arises from social behaviour. Most people are familiar with digital systems where users share their beliefs, opinions and even intentional lies (hoaxes). Also, systems modeling decision behaviour must account for those decisions dependance on the results of interactions with others within some social context. Spatial and mobile behaviour is exhibited by applications and data moving across (possibly nested) spaces defined by, for example, friend circles, groups, and shared folders. We therefore believe that a solid understanding of the notion of space and spatial mobility as well as the flow of epistemic information is relevant in many models of today’s distributed systems.

Constraint systems (cs’s) provide the basic domains and operations for the semantic foundations of the family of formal declarative models from concurrency theory known as concurrent constraint programming (ccp) process calculi [15]. Spatial constraint systems [9] (scs) are algebraic structures that extend cs for reasoning about basic spatial and epistemic behaviour such as extrusion and belief. Both spatial and epistemic assertions can be viewed as specific modalities. Other modalities can be used for assertions about time, knowledge and other concepts used in the specification and verification of concurrent systems.

The main goal of this PhD project is the study of the expressiveness of spatial constraint systems in the broader perspective of modal behaviour. In this summary, we shall show that

* This work was partially supported by INRIA-CORDI.
spatial constraint systems are sufficiently robust to capture other modalities and to derive new results for modal logic. We shall also discuss our future work on extending constraint systems to express fundamental epistemic behaviour such as knowledge and distributed knowledge.

This summary is structured as follows: In Section 2 we give some background. In Section 3 we present our results with applications to modal logic. In Sections 4 and 5 we describe ongoing work and future work for the remaining part of this PhD project. The results in this summary have been recently published as [7, 6].

2 Background

In this section we recall the notion of basic constraint system [3] and the more recent notion of spatial constraint system [9]. We presuppose basic knowledge of order theory and modal logic [1, 14, 5, 2].

The concurrent constraint programming model of computation [15] is parametric in a constraint system (cs) specifying the structure and interdependencies of the partial information that computational agents can ask of and post in a shared store. This information is represented as assertions traditionally referred to as constraints.

Constraint systems can be formalized as complete algebraic lattices [3]1. The elements of the lattice, the constraints, represent (partial) information. A constraint c can be viewed as an assertion (or a proposition). The lattice order \( \sqsubseteq \) is meant to capture entailment of information: \( c \sqsubseteq d \) alternatively written \( d \supseteq c \), means that the assertion d represents as much information as c. Thus, we may think of \( c \sqsubseteq d \) as saying that d entails c or that c can be derived from d. The least upper bound (lub) operator \( \sqcup \) represents join of information; \( c \sqcup d \), the least element in the underlying lattice above c and d. Thus, \( c \sqcup d \) can be seen as an assertion stating that both c and d hold. The top element represents the lub of all, possibly inconsistent, information, hence it is referred to as false. The bottom element true represents the empty information.

Definition 1 (Constraint Systems [3]). A constraint system (cs) \( C \) is a complete algebraic lattice \( (C, \sqsubseteq) \). The elements of Con are called constraints. The symbols \( \sqcup, \text{true} \) and \( \sqcap, \text{false} \) will represent the least upper bound ( lub ) operation, the bottom, and the top element of \( C \), respectively.

We shall use the following notions and notations from order theory.

Notation 2 (Lattices and Limit Preservation). Let \( C \) be a partially ordered set (poset) \( (C, \sqsubseteq) \). We shall use \( \bigsqcup S \) to denote the least upper bound ( lub ) (or supremum or join) of the elements in S, and \( \bigsqcap S \) is the greatest lower bound ( glb ) (infimum or meet) of the elements in S. We say that \( C \) is a complete lattice iff each subset of Con has a supremum and an infimum in Con. A non-empty set \( S \subseteq C \) is directed iff every finite subset of S has an upper bound in S. Also, \( c \in C \) is compact iff for any directed subset D of Con, \( c \subseteq \bigsqcup D \) implies \( c \subseteq d \) for some \( d \in D \). A complete lattice \( C \) is said to be algebraic iff for each \( c \in C \), the set of compact elements below it forms a directed set and the lub of this directed set is c. A self-map on Con is a function \( f : C \rightarrow C \). Let \( (C, \sqsubseteq) \) be a complete lattice. The self-map \( f \) on Con preserves the supremum of a set \( S \subseteq C \) iff \( f(\bigsqcup S) = \bigsqcup \{ f(c) \mid c \in S \} \). The preservation of the infimum of a set is defined analogously. We say \( f \) preserves finite/finite suprema iff it preserves the supremum of arbitrary finite/infinite sets. Preservation of finite/infinite infima is defined similarly.

---

1 An alternative syntactic characterization of cs, akin to Scott information systems, is given in [15].
2.1 Spatial Constraint Systems

The authors of [9] extended the notion of cs to account for distributed and multi-agent scenarios where agents have their own space for their local information and performing their computations.

Intuitively, each agent $i$ has a space function $[\cdot]_i$ from constraints to constraints. We can think of $[c]_i$, as an assertion stating that $c$ is a piece of information residing within a space attributed to agent $i$. An alternative epistemic logic interpretation of $[c]_i$ is an assertion stating that agent $i$ believes $c$ or that $c$ holds within the space of agent $i$ (but it may not hold elsewhere). Similarly, $[[c]_i]$ is a hierarchical spatial specification stating that $c$ holds within the local space the agent $i$ attributes to agent $j$. Nesting of spaces can be of any depth. We can think of a constraint of the form $[c]_i \sqcup [d]_j$ as an assertion specifying that $c$ and $d$ hold within two parallel/neighboring spaces that belong to agents $i$ and $j$, respectively.

Definition 3 (Spatial Constraint System [9]). An $n$-agent spatial constraint system (n-scs) $C$ is a cs $(Con, \sqsubseteq)$ equipped with $n$ self-maps $[\cdot]_1, \ldots, [\cdot]_n$ over its set of constraints $Con$ such that:

(S.1) $[true]_i = true$, and

(S.2) $[c \sqcup d]_i = [c]_i \sqcup [d]_i$ for each $c, d \in Con$.

Axiom S.1 requires $[\cdot]_i$ to be strict map (i.e. bottom preserving). Intuitively, it states that having an empty local space amounts to nothing. Axiom S.2 states that the information in a given space can be distributed. Notice that requiring S.1 and S.2 is equivalent to requiring that each $[\cdot]_i$ preserves finite suprema. Also, S.2 implies that $[\cdot]_i$ is monotonic: i.e., if $c \sqsubseteq d$ then $[c]_i \sqsupseteq [d]_i$.

2.2 Extrusion and utterance

We can also equip each agent $i$ with an extrusion function $\uparrow_i : Con \rightarrow Con$. Intuitively, within a space context $[\cdot]_i$, the assertion $\uparrow_i c$ specifies that $c$ must be posted outside of (or extruded from) agent $i$’s space. This is captured by requiring the extrusion axiom $[\uparrow_i c]_i = c$. In other words, we view extrusion/utterance as the right inverse of space/belief (and thus space/belief as the left inverse of extrusion/utterance).

Definition 4 (Extrusion). Given an n-scs $(Con, \sqsubseteq, [\cdot]_1, \ldots, [\cdot]_n)$, we say that $\uparrow_i$ is an extrusion function for the space $[\cdot]_i$ iff $\uparrow_i$ is a right inverse of $[\cdot]_i$, i.e., iff $[\uparrow_i c]_i = c$.

2.3 The Extrusion/Right Inverse Problem

A legitimate question is: Given space $[\cdot]_i$, can we derive an extrusion function $\uparrow_i$ for it? From set theory we know that there is an extrusion function (i.e., a right inverse) $\uparrow_i$ for $[\cdot]_i$ iff $[\cdot]_i$ is surjective. Recall that the pre-image of $y \in Y$ under $f : X \rightarrow Y$ is the set $f^{-1}(y) = \{x \in X \mid y = f(x)\}$. Thus, $\uparrow_i$ can be defined as a function, called choice function, that maps each element $c$ to some element from the pre-image of $c$ under $[\cdot]_i$.

3 Preliminary Results

In this part of the summary we shall describe the work we have achieved so far. It is based on the paper [7] recently accepted for publication.
Modal logics [14] extend classical logic to include operators expressing modalities. Depending on the intended meaning of the modalities, a particular modal logic can be used to reason about space, knowledge, belief or time, among others. Although the notion of spatial constraint system is intended to give an algebraic account of spatial and epistemic assertions, we shall show that it is sufficiently robust to give an algebraic account of more general modal assertions.

The aim of this part of the summary is the study of the extrusion problem for a meaningful family of scs’s that can be used as semantic structures for modal logics. They are called Kripke spatial constraint systems because its elements are Kripke Structures (KS’s). KS’s can be seen as transition systems with some additional structure on their states.

### 3.2 Constraint Frames and Normal Self Maps

Spatial constraint systems can be used, by building upon ideas from Geometric Logic and Heyting Algebras [16], as semantic structures for modal logic. We shall give an algebraic characterization of the concept of normal modality as maps preserving finite suprema.

First, recall that a Heyting implication \( c \rightarrow d \) in our setting corresponds to the weakest constraint one needs to join \( c \) with to derive \( d \): The greatest lower bound (glb) \( \{e \mid e \sqcup c \sqsubseteq d\} \). Similarly, the negation of a constraint \( c \), written \( \neg c \), can be seen as the weakest constraint inconsistent with \( c \), i.e., the glb \( \{e \mid e \sqcup c \sqsubseteq \text{false}\} = c \rightarrow \text{false} \).

▶ Definition 5 (Constraint Frames). A constraint system \((Con, \sqsubseteq)\) is said to be a constraint frame iff its joins distribute over arbitrary meets: More precisely, \( c \sqcup \bigcap S = \bigcap \{c \sqcup e \mid e \in S\} \) for every \( c \in Con \) and \( S \subseteq Con \). Given a constraint frame \((Con, \sqsubseteq)\) and \( c, d \in Con \), define Heyting implication \( c \rightarrow d \) as \( \bigcap \{e \in Con \mid c \sqcup e \sqsubseteq d\} \) and Heyting negation \( \neg c \) as \( c \rightarrow \text{false} \).

In modal logics one is often interested in normal modal operators. The formulae of a modal logic are those of propositional logic extended with modal operators. Roughly speaking, a modal logic operator \( m \) is normal iff (1) the formula \( m(\phi) \) is a theorem (i.e., true in all models for the underlying modal language) whenever the formula \( \phi \) is a theorem, and (2) the implication formula \( m(\phi \Rightarrow \psi) \Rightarrow (m(\phi) \Rightarrow m(\psi)) \) is a theorem. Thus, using Heyting implication, we can express the normality condition in constraint frames as follows.

▶ Definition 6 (Normal Maps). Let \((Con, \sqsubseteq)\) be a constraint frame. A self-map \( m \) on \( Con \) is said to be normal if (1) \( m(\text{true}) = \text{true} \) and (2) \( m(c \rightarrow d) \rightarrow (m(c) \rightarrow m(d)) = \text{true} \) for each \( c, d \in Con \).

The next theorem basically states that Condition (2) in Definition 6 is equivalent to the seemingly simpler condition: \( m(c \sqcup d) = m(c) \sqcup m(d) \).

▶ Theorem 7 (Normality & Finite Suprema). Let \( C \) be a constraint frame \((Con, \sqsubseteq)\) and let \( f \) be a self-map on \( Con \). Then \( f \) is normal if and only if \( f \) preserves finite suprema.

By applying the above theorem, we can conclude that space functions from constraint frames are indeed normal self-maps, since they preserve finite suprema.

### 3.3 Extrusion Problem for Kripke Constraint Systems

In this section we will study the extrusion/right inverse problem for a meaningful family of spatial constraint systems (scs’s), the Kripke scs. In particular, we shall derive and give
a complete characterization of normal extrusion functions as well as identify the weakest condition on the elements of the scs under which extrusion functions may exist. To illustrate the importance of this study, let us give some intuition first.

Kripke structures (KS) are a fundamental mathematical tool in logic and computer science. They can be seen as transition systems and they are used to give semantics to modal logics. Formally, a KS can be defined as follows.

Definition 8 (Kripke Structures). An n-agent Kripke Structure (KS) $M$ over a set of atomic propositions $\Phi$ is a tuple $(S, \pi, \mathcal{R}_1, \ldots, \mathcal{R}_n)$ where $S$ is a nonempty set of states, $\pi : S \to (\Phi \to \{0, 1\})$ is an interpretation associating with each state a truth assignment to the primitive propositions in $\Phi$, and $\mathcal{R}_j$ is a binary relation on $S$. A pointed KS is a pair $(M, s)$ where $M$ is a KS and $s$, called the actual world, is a state of $M$. We write $s \mathrel{\rightarrow_M} t$ to denote $(s,t) \in \mathcal{R}_i$.

We now define the Kripke scs wrt a set $\mathcal{S}_n(\Phi)$ of pointed KS.

Definition 9 (Kripke Spatial Constraint Systems [9]). Let $\mathcal{S}_n(\Phi)$ be a non-empty set of n-agent Kripke structures over a set of primitive propositions $\Phi$. We define the Kripke n-scs for $\mathcal{S}_n(\Phi)$ as $K(\mathcal{S}_n(\Phi)) = (\text{Con}, \sqsubseteq, [1], \ldots, [n])$ where $\text{Con} = \mathcal{P}(\Delta)$, $\sqsubseteq = \sqsupseteq$, and

\[ [c]_i \overset{\text{def}}{=} \{(M,s) \in \Delta \mid \mathrel{\triangleright_i (M,s) \subseteq c}\} \]

where $\Delta$ is the set of all pointed Kripke structures $(M,s)$ such that $M \in \mathcal{S}_n(\Phi)$ and $\mathrel{\triangleright_i (M,s) = \{(M,t) \mid s \mathrel{\rightarrow_M} t\}}$ denotes the pointed KS reachable from $(M,s)$.

The structure $K(\mathcal{S}_n(\Phi)) = (\text{Con}, \sqsubseteq, [1], \ldots, [n])$ is a complete algebraic lattice given by a powerset ordered by reversed inclusion $\sqsubseteq$. The join $\sqcup$ is set union, the top element $false$ is the empty set $\emptyset$, and bottom true is the set $\Delta$ of all pointed Kripke structures $(M,s)$ with $M \in \mathcal{S}_n(\Phi)$. Notice that $K(\mathcal{S}_n(\Phi))$ is a frame since meets are unions and joins are intersections so the distributive requirement is satisfied. Furthermore, each $[1]_i$ preserves arbitrary suprema (intersection) and thus, from Theorem 7 it is a normal self-map.

3.4 Existence of Right Inverses

We shall now address the question of whether a given Kripke constraint system can be extended with extrusion functions. We shall identify a sufficient and necessary condition on accessibility relations for the existence of an extrusion function $\uparrow_i$ given the space $[1]_i$.

Definition 10 (Determinacy and Unique-Determinacy). Let $S$ and $\mathcal{R}$ be the set of states and an accessibility relation of a KS $M$, respectively. Given $s, t \in S$, we say that $s$ determines $t$ wrt $\mathcal{R}$ if $(s,t) \in \mathcal{R}$. We say that $s$ uniquely determines $t$ wrt $\mathcal{R}$ if $s$ is the only state in $S$ that determines $t$ wrt $\mathcal{R}$. A state $s \in S$ is said to be determinant wrt $\mathcal{R}$ if it uniquely determines some state in $S$ wrt $\mathcal{R}$. Furthermore, $\mathcal{R}$ is determinant-complete if every state in $S$ is determinant wrt $\mathcal{R}$.

Example 11. Figure 1 illustrates some determinant-complete accessibility relations. Figures 1.(i) and 1.(iii) are determinant-complete accessibility relations. Figure 1.(ii) shows a non-determinant-complete accessibility relation (the transitive closure of an infinite line structure).

Notation 12. We write $s \mathrel{\rightarrow_M^i} t$ for $s$ uniquely determines $t$ wrt $\mathrel{\rightarrow_M^i}$.
The following theorem provides a complete characterization, in terms of classes of KS, of the existence of right inverses for space functions.

**Theorem 13 (Completeness).** Let \([\cdot]_i\) be a spatial function of a Kripke scs \(K(S)\). Then \([\cdot]_i\) has a right inverse if and only if for every \(M \in S\) the accessibility relation \(\xrightarrow{i} M\) is determinant-complete.

Henceforth we use \(M^0\) to denote the class of KS’s whose accessibility relations are determinant-complete. It follows from Theorem 13 that \(S = M^0\) is the largest class for which space functions of a Kripke scs \(K(S)\) have right inverses.

### 3.5 Right Inverse Constructions

Let \(K(S) = (\text{Con}, \sqsubseteq, [\cdot]_1, \ldots, [\cdot]_n)\) be a Kripke scs. The Axiom of Choice and Theorem 13 tell us that each \([\cdot]_i\) has a right inverse (extrusion function) if and only if \(S \subseteq M^0\). We are interested, however, in explicit constructions of the right inverses.

Since any Kripke scs space function preserves arbitrary suprema, we obtain the following canonical greatest right-inverse construction. Recall that the pre-image of \(c\) under \([\cdot]_i\) is given by the set \([c]_i^{-1} = \{d | c = [d]_i\}\).

**Definition 14 (Max Right Inverse).** Let a Kripke scs \(K(S) = (\text{Con}, \sqsubseteq, [\cdot]_1, \ldots, [\cdot]_n)\) be defined over \(S \subseteq M^0\). We define \(\uparrow^M_i\) as the following self-map on \(\text{Con} : \uparrow^M_i : c \mapsto \bigsqcup [c]_i^{-1}\).

Then \(\uparrow^M_i\) is a right inverse for \([\cdot]_i\), and from its definition it is clear that \(\uparrow^M_i\) is the greatest right inverse of \([\cdot]_i\) wrt \(\sqsubseteq\). However, \(\uparrow^M_i\) is not necessarily normal in the sense of Definition 6.

In what follows we shall identify right inverse constructions that are normal.

### 3.6 Normal Right Inverses

The following central lemma provides distinctive properties of any normal right-inverse.

**Lemma 15.** Let \(K(S) = (\text{Con}, \sqsubseteq, [\cdot]_1, \ldots, [\cdot]_n)\) be the Kripke scs over \(S \subseteq M^0\). Suppose that \(f\) is a normal right-inverse of \([\cdot]_i\). Then for every \(M \in S\), \(c \in \text{Con}\):

(i) \(\triangledown_i(M, s) \subseteq f(c)\) if \((M, s) \in c\),
(ii) \(\{ (M, t) \} \subseteq f(c)\) if \(t\) is multiply determined wrt \(\xrightarrow{i} M\), and
(iii) \(\text{true} \subseteq f(\text{true})\).

The above property tell us what sets should necessarily be included in every \(f(c)\) if \(f\) is to be both normal and a right-inverse of \([\cdot]_i\).
We then say that Section 3.5 interpret the reverse modality in grammar. KS's extend it with modalities formulae are interpreted in an arbitrary Kripke scs over $S \subseteq \mathcal{M}$. We define the max normal right-inverse for agent $i$, $\uparrow_{i}^{\text{max}}$ as the following self-map on $S \subseteq M$.

$$\uparrow_{i}^{\text{max}}(c) \overset{\text{def}}{=} \begin{cases} \text{true} & \text{if } c = \text{true} \\ \{ (M, t) \mid t \text{ is determined wrt } \xrightarrow{i} \text{ and } \forall s : s \xrightarrow{i} t, (M, s) \in c \} & \end{cases}$$

Notice that $\uparrow_{i}^{\text{max}}(c)$ excludes indetermined states (i.e., a state $t$ such that for every $s \in S$, $(s, t) \notin R$.) If $c \neq \text{true}$, it turns out that we can add them and obtain a more succinct normal right-inverse:

**Definition 17 (Normal Right-Inverse).** Let $\mathbf{K}(S) = (\text{Con}, \subseteq, \{1\}, \ldots, \{n\})$ be a Kripke scs over $S \subseteq \mathcal{M}$. Define $\uparrow_{i}^{\text{R}} : \text{Con} \rightarrow \text{Con}$ as $\uparrow_{i}^{\text{R}}(c) \overset{\text{def}}{=} \{ (M, t) \mid \forall s : s \xrightarrow{i} t, (M, s) \in c \}$.

Clearly $\uparrow_{i}^{\text{R}}(c)$ includes every $(M, t)$ such that $t$ is indetermined wrt $\xrightarrow{i}$.

### 3.7 Applications

In this section we will illustrate and briefly discuss the results obtained in the previous section in the context of modal logic.

We can interpret modal formulae as constraints in a given Kripke scs $C = \mathbf{K}(S_{n}(\Phi))$.

**Definition 18 (Kripke Constraint Interpretation).** Let $C$ be a Kripke scs $\mathbf{K}(S_{n}(\Phi))$. Given a modal formula $\phi$ in the modal language $\mathcal{L}_{\Phi}(\Phi)$, its interpretation in the Kripke scs $C$ is the constraint $C[\phi]$ indutively defined as follows: $C[p] = \{ (M, s) \mid \pi_{M}(s)(p) = 1 \}$, $C[\phi \land \psi] = C[\phi] \sqcup C[\psi]$, $C[\neg \phi] = \sim C[\phi]$, $C[\Box \phi] = \{ C[\phi] \}$.

To illustrate our results in the previous sections, we fix a modal language $\mathcal{L}_{\Phi}(\Phi)$ (whose formulae are) interpreted in an arbitrary Kripke scs $\mathbf{C} = \mathbf{K}(S_{n}(\Phi))$. Suppose we wish to extend it with modalities $\Box_{i}^{-1}$, called reverse modalities also interpreted over the same set of KS's $S_{n}(\Phi)$ and satisfying some minimal requirement. The language is given by the following grammar.

**Definition 19 (Modal Language with Reverse Modalities).** Let $\Phi$ be a set of primitive propositions. The modal language $\mathcal{L}_{\Phi}^{\Box_{i}^{-1}}$ is given by the following grammar: $\phi, \psi, \ldots ::= p \mid \phi \land \psi \mid \neg \phi \mid \Box_{i}\phi \mid \Box_{i}^{-1}\phi$ where $p \in \Phi$ and $i \in \{1, \ldots, n\}$.

The minimal semantic requirement for each $\Box_{i}^{-1}$ is that:

$$\Box_{i} \Box_{i}^{-1}\phi \leftrightarrow \phi \quad \text{valid in } S_{i}(\Phi).$$

We then say that $\Box_{i}^{-1}$ is a right-inverse modality for $\Box_{i}$.

Since $C[\Box_{i} \phi] = \{ C[\phi] \}$, we can derive semantic interpretations for $\Box_{i}^{-1}\phi$ by using a right inverse $\uparrow_{i}$ for $\{1\}$, in Definition 18. Assuming that such a right inverse exists, we can interpret the reverse modality in $C$ as

$$C[\Box_{i}^{-1}\phi] = \uparrow_{i}( C[\phi] ).$$

We can choose $\uparrow_{i}$ in Equation (3) from the set $\{\uparrow_{i}, \uparrow_{i}^{\text{max}}, \uparrow_{i}^{\text{R}}\}$ of right-inverses given in Section 3.5.
### 3.7.1 Temporal Operators

We conclude this section with a brief discussion on some right-inverse linear-time modalities. Let us suppose that \( n = 2 \) in our modal language \( \mathcal{L}_n(\Phi) \) under consideration (thus interpreted in Kripke scs \( \mathcal{C} = \mathcal{K}(S_2(\Phi)) \)). Assume further that the intended meaning of the two modalities \( \square_1 \) and \( \square_2 \) are the next operator (\( \circ \)) and the henceforth/always operator (\( \square \)), respectively, in a linear-time temporal logic. To obtain the intended meaning we take \( S_2(\Phi) \) to be the largest set such that: If \( M \in S_2(\Phi) \), \( M \) is a 2-agent KS where \( \rightarrow_M \) is isomorphic to the successor relation on the natural numbers and \( \rightarrow_M^2 \) is the reflexive and transitive closure of \( \rightarrow_M \). The relation \( \rightarrow_M \) is intended to capture the linear flow of time. Intuitively, \( s \rightarrow_M t \) means \( t \) is the only next state for \( s \). Similarly, \( s \rightarrow_M^2 t \) for \( s \neq t \) is intended to capture the fact that \( t \) is one of the infinitely many future states for \( s \).

Let us first consider the next operator \( \square_1 = \circ \). Notice that \( \rightarrow_M \) is determinant-complete. If we apply Equation (3) with \( \uparrow_1 = \uparrow_1^\circ \), we obtain \( \square_1^{-1} = \circ \), a past modality known in the literature as strong previous operator [13]. If we take \( \uparrow_1 \) to be the normal right inverse \( \uparrow_1^n \), we obtain \( \square_1^{-1} = \circ \), the past modality known as weak previous operator [13]. Notice that the only difference between the two operators is that, if \( s \) is an indetermined/initial state \( s \rightarrow_M \) then \( (M,s) \not\models \circ \phi \) and \( (M,s) \models \circ \phi \) for any \( \phi \). It follows that \( \circ \) is not a normal operator, since \( \circ T \) is not valid in \( S_2(\Phi) \) but \( T \) is.

Let us now consider the always operator \( \square_2 = \circ \). Notice that \( \rightarrow_M^2 \) is not determinant-complete: Take any increasing chain \( s_0 \rightarrow_M s_1 \rightarrow_M s_2 \rightarrow_M \ldots \). The state \( s_1 \) is not determinant because for every \( s_j \) such that \( s_1 \rightarrow_M s_j \) we also have \( s_0 \rightarrow_M s_j \). Theorem 13 tells us that there is no right-inverse \( \uparrow_2 \) of \( \rightarrow_2 \) that can give us an operator \( \square_2^{-1} \) satisfying Equation (2).

### 4 Ongoing Work

#### 4.1 Knowledge in Terms of Space

In this section we show our current work on using spatial constraint systems to express the epistemic concept of knowledge by using the following notion of global information:

**Definition 20 (Global Information).** Let \( C \) be an \( n \)-scs with space functions \([\cdot]_1, \ldots, [\cdot]_n\) and \( G \) be a non-empty subset of \([1, \ldots, n]\). Group-spaces \([\cdot]_G\) and global information \( [\cdot]_G \) of \( G \) in \( C \) are defined as:

\[
[c]_G \overset{\text{def}}{=} \bigsqcup_{i \in G} [c]_i \quad \text{and} \quad [c]_G \overset{\text{def}}{=} \bigsqcup_{j=0}^{\infty} [c]_G^j
\]

for all \( c \in C \) (4)

where \( [c]_0 \overset{\text{def}}{=} c \) and \( [c]_G^{k+1} \overset{\text{def}}{=} [c]_G^k \).

The constraint \( [c]_G \) means that \( c \) holds in the spaces of agents in \( G \). The constraint \( [c]_G \) entails \([\ldots[c]_{i_m} \ldots c]_{i_1}\) for any \( i_1, i_2, \ldots, i_m \in G \). Thus, it realizes the intuition that \( c \) holds globally wrt \( G \): \( c \) holds in each nested space involving only the agents in \( G \). In particular, if \( G \) is the set of all agents, \( [c]_G \) means that \( c \) holds everywhere. From the epistemic point of view \( [c]_G \) is related to the notion of common-knowledge of \( c \) [5].

#### 4.2 Knowledge Constraint System

In [9] the authors extended the notion of spatial constraint system to account for knowledge. In this summary we shall refer to the extended notion in [9] as \( S_4 \) constraint systems since it
is meant to capture the epistemic logic for knowledge S4. Roughly speaking, one may wish to use \([c_i]\) to represent not only some information \(c\) that agent \(i\) has but rather a fact that he knows. The domain theoretical nature of constraint systems allows for a rather simple and elegant characterization of knowledge by requiring space functions to be Kuratowski closure operators [10]: i.e., monotone, extensive and idempotent maps preserving bottom and lubs.

**Definition 21** (Knowledge Constraint System [9]). An \(n\)-agent S\(4\) constraint system (\(n\)-s\(4\)cs) \(C\) is an \(n\)-scs whose space functions \([[1]], \ldots, [[n]]\) are also closure operators. Thus, in addition to S.1 and S.2 in Definition 3, each \([[i]]\), also satisfies:

\[(EP.1)\] \([[[i]]]\) \(\supseteq c\) and

\[(EP.2)\] \([[[[i]]]] = [[[i]]],\)

Intuitively, in an \(n\)-s\(4\)cs, \([[i]]\) states that the agent \(i\) has knowledge of \(c\) in its store \([[i]]\). The axiom \(EP.1\) says that if agent \(i\) knows \(c\) then \(c\) must hold, hence \([[i]]\) has at least as much information as \(c\). The epistemic principle that an agent \(i\) is aware of its own knowledge (the agent knows what he knows) is realized by \(EP.2\). Also, the epistemic assumption that agents are idealized reasoners follows from the monotonicity of space functions, i.e., for a consequence \(c\) of \(d\) (\(d \supseteq c\)), then if \(d\) is known to agent \(i\), so is \(c\), \([[d]] i \supseteq [[i]]\).

In [9] the authors use the notion of Kuratowski closure operators \([[i]]\), to capture knowledge. In what follows we show an alternative interpretation of knowledge as the global construct \([[c]]_G\) in Definition 20.

### 4.3 Knowledge as Global Information

Let \(C = (Con, \subseteq, [[[1]]], \ldots, [[[n]]])\) be a spatial constraint system. From Definition 20 we obtain the following equation:

\[ [[c]]_{\{i\}} = c \cup [[[i]]] \cup [[[i]]]^2 \cup [[[i]]]^3 \cup \ldots = \bigcup_{j=0}^{\infty} [[[i]]]^j \]  

(5)

For simplicity, we shall use \([[c]]_i\) as an abbreviation of \([[c]]_{\{i\}}\). We shall demonstrate that \([[c]]_i\) can also be used to represent the knowledge of \(c\) by agent \(i\).

We will show that the global function \([[c]]_i\) is in fact a Kuratowski closure operator and thus satisfies the epistemic axioms \(EP.1\) and \(EP.2\) above: It is easy to see that \([[c]]_i\) satisfies \([[c]]_i \supseteq c\) (\(EP.1\)). Under certain natural assumptions we shall see that it also satisfies \([[c]]_i \supseteq [[[c]]_i\], \([[c]]_i\) (\(EP.2\)). Furthermore, we can combine knowledge with our belief interpretation of space functions: clearly, \([[c]]_i \supseteq [[[c]]_i]_i\) holds for any \(c\). This reflects the epistemic principle that whatever is known is also believed [8].

We now show that any spatial constraint system with continuous space functions (i.e. functions preserving lubs of any directed set) \([[1]]_1, \ldots, [[n]]_n\) induces an s\(4\)cs with space functions \([[1]]_1, \ldots, [[n]]_n\).

**Definition 22.** Given an scs \(C = (Con, \subseteq, [[[1]]], \ldots, [[[n]]])\), we use \(C^*\) to denote the tuple \((Con, \subseteq, [[[1]]], \ldots, [[[n]]])\).

One can show that \(C^*\) is also a spatial constraint system. Besides, it is an s\(4\)cs as stated next.

**Theorem 23.** Let \(C = (Con, \subseteq, [[[1]]], \ldots, [[[n]]])\) be a spatial constraint system. If \([[1]]_1, \ldots, [[n]]_n\) are continuous functions, then \(C^*\) is an \(n\)-agent s\(4\)cs.
We shall now prove that S4 can also be captured using the global interpretation of space. From now on C denotes the Kripke constraint system \( \mathbf{K}(\mathcal{M}) \) (Definition 9), where \( \mathcal{M} \) represents a set of non-empty set of n-agent Kripke structures. Notice that constraints in C, and consequently also in \( \mathbf{C}^* \), are sets of \textit{unrestricted} (pointed) Kripke structures. Although C is not an S4sc, from the above theorem, its induced scs \( \mathbf{C}^* \) is. Also, we can give in \( \mathbf{C}^* \) a sound and complete compositional interpretation of S4 formulae.

The compositional interpretation of modal formulae in our constraint system \( \mathbf{C}^* \) is similar to the one introduced in 18 except for the interpretation of the \( \square_i \phi \) modality. Informally, \( \square_i \phi \) says that, if a given agent \( i \) knows \( \phi \) then if we were to communicate with each other we could have \( \phi \) in common, and consequently also in \( \mathbf{DK^*} \) if.

\[ \mathbf{C}^* [\square_i \phi] = \bigcup_{j=0}^\omega [\mathbf{C}^* [\phi]]^j_i \]

In particular, from Theorem 23 and Axiom EP.2, \( \mathbf{C}^* [\square_i \phi] = \mathbf{C}^* [\square_i (\square_i \phi)] \) follows as an S4-knowledge modality; i.e., if agent \( i \) knows \( \phi \) he knows that he knows it.

We conclude this section with the following theorem stating the correctness wrt validity of the interpretation of knowledge as as global operator.

\[ \text{Theorem 24. } \mathbf{C}^* [\phi] = \text{true if and only if } \phi \text{ is S4-valid.} \]

## 5 Future Work

As future work we are planning to specify the epistemic notion of \textit{Distributed Knowledge} (DK) [5] as well as a computational notion of \textit{process} in our algebraic structures.

### 5.1 Distributed Knowledge in Terms of Space

Informally, DK says that, if a given agent \( i \) has \( c \rightarrow d \) in his space and an agent \( j \) has \( c \) in her space, then if we were to communicate with each other we could have \( d \) in their space though individually neither \( i \) nor \( j \) has \( d \). This could be an important concept for distributed systems, e.g. to predict unwanted behavior in a system upon potential communication among agents.

Using [5] and our notion of Heyting implication in Definition 5 we could extend scs with DK as follows.

\[ \text{Definition 25. } \text{Let } \mathcal{C} = (\text{Con}, \subseteq, [\_], \ldots, [\_]). \text{ Let } G \subseteq \{1,2,\ldots,n\} \text{ be a non-empty subset of agents. Distributed knowledge of } G \text{ is a self-map } \mathcal{D}_G : \text{Con} \rightarrow \text{Con} \text{ satisfying the next axioms:} \]

1. \( \mathcal{D}_G(\text{true}) = \text{true} \)
2. \( \mathcal{D}_G(c \cup d) = \mathcal{D}_G(c) \cup \mathcal{D}_G(d) \)
3. \( \mathcal{D}_G(c) = [c]_i \text{ if } G = \{i\} \)
4. \( \mathcal{D}_G(c) \sqsupseteq \mathcal{D}_G(d) \text{ if } G' \subseteq G \)

Intuitively \( \mathcal{D}_G(c) \) means that \( G \) has DK of \( c \). The first condition says that any \( G \) has DK of \text{true}. The second condition says that, if \( G \) has DK of two pieces of information \( c \) and \( d \), then \( G \) has DK of their join. The third condition tells us that an agent has DK of what he knows. Finally, the fourth condition says that the larger the subgroup, the greater its DK.

In previous paragraphs we argued that if agent \( i \) has \( c \rightarrow d \) and an agent \( j \) has \( c \) then they would have DK of \( d \) (\( \mathcal{D}_{\{i,j\}}(d) \)). Indeed, from the above axioms and the properties of space, one can prove that \( [c \rightarrow d]_i \cup [c]_j \sqsupseteq \mathcal{D}_{\{i,j\}}(d) \).
As future work we would like to give an explicit spatial construction that characterizes \( D_G(c) \).

### 5.2 Processes as Constraint Systems

Concurrent constraint programming (ccp) calculi are a well-known family of process algebras from concurrency theory \[15, 12, 4, 11\]. Computational processes from ccp can be seen as closure operators over an underlying constraint system \( C = (\text{Con}, \sqsubseteq) \). A closure operator \( f \) over \( C \) is a monotonic self map on \( \text{Con} \) such that \( f(c) \sqsubseteq c \) and \( f(f(c)) = f(c) \).

It is well known that closure operators form themselves a complete lattice. Thus, ccp processes can be interpreted as elements of the cs \( C^+ \) where \( C^+ \) is the set of closure operators over \( \text{Con} \) ordered wrt \( \sqsubseteq \) (recall that \( f \sqsubseteq g \) iff \( f(c) \sqsubseteq g(c) \) for every \( c \in \text{Con} \)).

We plan to use the space and extrusion functions from spatial constraint systems to give a declarative semantics to the corresponding spatial, time and extrusion constructs in ccp-based process algebras. More importantly, we plan to use the notion of distributed knowledge to derive a corresponding notion in ccp-process algebras. To our knowledge this will be the first time that distributed knowledge is used in the context of process calculi.
