Abstract

In the Embedded Planar Diameter Improvement problem (EPDI) we are given a graph $G$ embedded in the plane and a positive integer $d$. The goal is to determine whether one can add edges to the planar embedding of $G$ in such a way that planarity is preserved and in such a way that the resulting graph has diameter at most $d$. Using non-constructive techniques derived from Robertson and Seymour’s graph minor theory, together with the effectivization by self-reduction technique introduced by Fellows and Langston, one can show that EPDI can be solved in time $f(d) \cdot |V(G)|^{O(1)}$ for some function $f(d)$. The caveat is that this algorithm is not strongly uniform in the sense that the function $f(d)$ is not known to be computable. On the other hand, even the problem of determining whether EPDI can be solved in time $f_1(d) \cdot |V(G)|^{f_2(d)}$ for computable functions $f_1$ and $f_2$ has been open for more than two decades [Cohen at. al. Journal of Computer and System Sciences, 2017]. In this work we settle this later problem by showing that EPDI can be solved in time $f(d) \cdot |V(G)|^{O(d)}$ for some computable function $f$. Our techniques can also be used to show that the Embedded k-outerplanar Diameter Improvement problem (k-EOPDI), a variant of EPDI where the resulting graph is required to be $k$-outerplanar instead of planar, can be solved in time $f(d) \cdot |V(G)|^{O(k)}$ for some computable function $f$. This shows that for each fixed $k$, the problem $k$-EOPDI is strongly uniformly fixed parameter tractable with respect to the diameter parameter $d$.

1 Introduction

In this work, a plane graph is a pair \( G^g = (G, g) \) consisting of a planar graph \( G \) together with a planar embedding \( g \) of \( G \) \(^4\). In the embedded planar diameter improvement problem (EPDI), we are given a plane graph \( G^g \) and a positive integer \( d \), and the goal is to determine whether \( G^g \) has a plane supergraph \( H^b \) of diameter at most \( d \). The set of yes instances of EPDI is closed under minors. In other words, if \( G^g \) has a plane supergraph of diameter at most \( d \), then any minor of \( G^g \) also has such a supergraph. Therefore, using non-constructive arguments from Robertson and Seymour’s graph minor theory [14, 15] in conjunction with the fact that planar graphs of constant diameter have constant treewidth, one can show that for each fixed \( d \), there exists an algorithm \( A_d \) which determines in linear time whether a given plane graph \( G^g \) has a plane supergraph of diameter at most \( d \). The caveat is that the non-constructive techniques mentioned above provide us with no clue about what the algorithm \( A_d \) actually is. This problem can be partially remedied using a technique called effectivization by self-reduction introduced by Fellows and Langston [10, 8].

Using this technique one can show that for some function \( f : \mathbb{N} \to \mathbb{N} \), there exists a single algorithm \( A \) which takes a plane graph \( G^g \) and a positive integer \( d \) as input, and determines in time \( f(d) \cdot |V(G)|^{O(1)} \) whether \( G^g \) has a plane supergraph of diameter at most \( d \). Nevertheless, the function \( f : \mathbb{N} \to \mathbb{N} \) bounding the influence of the parameter \( d \) in the running time of the algorithm mentioned above is not known to be computable. The problem of determining whether EPDI admits an algorithm running in time \( f(d) \cdot |V(G)|^{O(1)} \) for some computable function \( f \) is a notorious and long-standing open problem in parameterized complexity theory [8, 9, 5]. Interestingly even the problem of determining whether EPDI can be solved in time \( f_1(d) \cdot |V(G)|^{O_1(d)} \) for computable functions \( f_1 \) and \( f_2 \) has remained open until now [4]. In this work we settle this latter problem by showing that EPDI can be solved in time \( 2^{O(d)} \cdot |V(G)|^{O(d)} \). The problem of determining whether EPDI can be solved in time \( f(d) \cdot |V(G)|^{O(1)} \) for some computable function \( f : \mathbb{N} \to \mathbb{N} \) remains widely open.

> Theorem 1. There is an algorithm \( A \) that takes as input, a positive integer \( d \), and a plane graph \( G^g \), and determines in time \( 2^{d^{O(d)}} \cdot |V(G)|^{O(d)} \) whether \( G^g \) has a plane supergraph \( H^b \) of diameter at most \( d \).

A graph is 1-outerplanar if it can be embedded in the plane in such a way that every vertex lies in the outer face of the embedding. A graph is \( k \)-outerplanar if it can be embedded in the plane in such a way that after deleting all vertices in the outer face, the remaining graph is \((k-1)\)-outerplanar. In [4] Cohen et al. have considered the \( k \)-outerplanar diameter improvement problem \((k\text{-OPDI})\), a variant of the PDI problem in which the target supergraph is required to be \( k \)-outerplanar instead of planar. In particular, they have shown that the \( 1 \)-OPDI problem can be solved in polynomial time. The complexity of the \( k \)-OPDI problem with respect to explicit algorithms was left as an open problem for \( k \geq 2 \). By adapting our algorithm for the EPDI problem we are able to show that when the input graph is given together with an embedding that must be preserved, then the resulting problem, the \( k \)-EOPDI problem, can be solved in time \( 2^{d^{O(d)}} \cdot |V(G)|^{O(k)} \) for each fixed \( k \).

In other words, this problem is strongly uniformly fixed parameter tractable with respect to the diameter parameter for each fixed value of outerplanarity.

\(^4\) See Section 2 for formal definitions.
Theorem 2. There is an algorithm \( \mathcal{A} \) that takes as input, positive integers \( d, k \), and a plane graph \( G^9 \), and determines in time \( 2^{d^{O(d)}} \cdot |V(G)|^{O(k)} \) whether \( G^9 \) has a \( k \)-outerplanar plane supergraph \( H^b \) of diameter at most \( d \).

Related Work. In the planar diameter improvement problem (PDI), the input consists of a planar graph \( G \) and a positive integer \( d \) and the goal is to determine whether one can add edges to \( G \) in such a way that the resulting graph is planar and has diameter at most \( d \). Note that the difference between EPDI and PDI is that in the former we are given an embedding that must be preserved, while in the latter no embedding is given at the input. Recently, using automata theoretic techniques, the second author was able to provide strongly uniform FPT and XP algorithms for many graph completion problems where the parameter to be improved is definable in counting monadic second order logic [6]. In particular, when specialized to the PDI problem, the techniques in [6] yield a strongly uniform algorithm that solves PDI in time \( f(d) \cdot 2^{O(\Delta d)} \cdot |V(G)|^{O(d)} \), where \( f \) is a computable function and \( \Delta \) is the maximum degree of the input graph \( G \). Nevertheless, the problem of determining whether PDI admits a strongly uniform algorithm running in time \( f_1(d) \cdot |V(G)|^{f_2(d)} \) for computable functions \( f_1 \) and \( f_2 \) is still open if no bound is imposed on the degree of the input graph. We note that currently it is not known either whether PDI is reducible to EPDI or whether EPDI is reducible to PDI in XP time. Therefore it is not clear if our algorithm for EPDI can be used to provide a strongly uniform XP algorithm for PDI. It is worth noting that no hardness results for either PDI or EPDI are known. Indeed, determining whether either of these problems is NP-hard is also a long-standing open problem.

While the techniques employed in [6] to tackle the PDI problem on graphs of bounded degree are automata theoretic, the techniques employed in the present work to tackle the EPDI problem on general graphs are based on dynamic programming. In particular, our main algorithm carefully exploits the view of separators in plane graphs as nooses - simple closed curves in the plane that touch the graph only in the vertices (see e.g. [2]). The terminology noose for such curves comes from the graph minors project of Robertson and Seymour [13]. Our algorithm processes nooses in a way reminiscent of the dynamic programming algorithm of Bouchitte and Todinca over potential maximal cliques [3]. Although this method has found numerous applications in the field of graph algorithms [7, 12, 11], this work is the first which apply these techniques in the context of completion problems.

For each fixed \( d \), let \( G_d^9 \) be the subgraph-closure\(^5\) of the class of planar graphs of diameter at most \( d \). Then clearly a graph \( G \) is a yes instance of PDI if and only if \( G \in G_d^9 \). When considering the task of constructing strongly uniform algorithms for PDI, two general approaches come to mind. The first follows by observing that graphs in \( G_d^9 \) have treewidth at most \( O(d) \), and that for each fixed \( d \in \mathbb{N} \), \( G_d^9 \) is MSO definable. Therefore, one could try to devise an algorithm \( \mathcal{A} \) that takes an integer \( d \) as input and constructs an MSO formula \( \varphi_d \) defining \( G_d^9 \). With such a formula \( \varphi_d \) in hands, one could apply Courcelle’s model checking theorem to determine whether a given graph \( G \) is a yes instance of PDI. The existence of such an algorithm \( \mathcal{A} \) is however an open problem. We note that one can easily define by induction on \( d \) an MSO sentence \( \phi_d \) which is true on a graph \( G \) if and only if \( G \) is planar and has diameter at most \( d \). Nevertheless, it is not clear how to use \( \phi_d \) to construct \( \varphi_d \). It is worth noting that there is no algorithm that takes an MSO sentence \( \varphi \) as input and constructs a sentence \( \varphi' \) defining the subgraph closure of the models of \( \varphi \). For instance, let

\[^5\] Note that the class of planar graphs of diameter at most \( d \) is closed under contractions but not under subgraphs, since removing edges may increase the diameter.
\[ \mathcal{L} = \{ L_n \}_{n \in \mathbb{N}} \] be the family of ladder graphs, where \( L_n \) is the ladder with \( n \) steps. It is easy to see that \( \mathcal{L} \) is MSO definable and every graph in \( \mathcal{L} \) has treewidth at most 2. Nevertheless, the subgraph closure of \( \mathcal{L} \) does not have finite index. Therefore, such subgraph closure is not MSO definable, since Courcelle’s theorem implies that MSO-definable families of graphs of bounded treewidth have finite index.

The second approach is based on the fact that for each fixed \( d \in \mathbb{N} \), the set of graphs \( \mathcal{G}_d \) is minor closed. In particular, this implies that the class \( \mathcal{G}_d \) can be characterized by a finite set \( \mathcal{M}_d \) of forbidden minors. Therefore, one could try to devise an effective algorithm that takes an integer \( d \in \mathbb{N} \) as input and gives as output the list of all forbidden minors in \( \mathcal{M}_d \). By using the fact that minor-freeness can be tested in time FPT in the size of the minors, such an algorithm \( \mathcal{A} \) would solve PDI in time FPT in \( d \). We observe however that the problem of listing the elements of \( \mathcal{M}_d \) may be much more difficult than the problem of solving PDI in time FPT in \( d \). It is worth noting that Adler, Kreutzer and Grohe have shown that if a minor-free graph property \( \mathcal{P} \) is MSO definable and has constant treewidth, then one can effectively enumerate the set of forbidden minors for \( \mathcal{P} \) [1]. Nevertheless, the problem with this approach is that, as discussed in the previous paragraph, it is not clear how to construct an MSO sentence \( \varphi_d \) defining \( \mathcal{G}_d \).

## 2 Preliminaries

**Graphs.** For each \( n \in \mathbb{N} \) we let \([n] = \{ 1, ..., n \} \). For each finite set \( S \) we let \( \mathcal{P}(S, 2) = \{ \{ u, v \} \subseteq S \mid u \neq v \} \) be the set of unordered pairs of elements from \( S \). In this work, a graph is a pair \( G = (V(G), E(G)) \) where \( V(G) \) is a finite set of vertices and \( E(G) \subseteq \mathcal{P}([n], 2) \) is a set of undirected edges. A path of length \( m \) in \( G \) is a sequence \( p = v_0v_1...v_m \) of distinct vertices where for each \( i \in \{ 0, ..., m - 1 \} \), \( \{ v_i, v_{i+1} \} \in E(G) \). We say that \( v_0 \) and \( v_m \) are the endpoints of \( p \). The distance \( \text{dist}(u, v) \) between vertices \( u \) and \( v \) is defined as the length of the shortest path with endpoints \( u \) and \( v \). The diameter of \( G \), is defined as \( d(G) = \max_{u, v} \text{dist}(u, v) \).

**Embeddings.** A simple arc in \( \mathbb{R}^2 \) is a subset \( \alpha \subseteq \mathbb{R}^2 \) that is a homeomorphic image of the closed real interval \([0, 1]\). We let \( \text{endpts}(\alpha) \) be the endpoints of \( \alpha \), and \( \text{Int}(\alpha) = \alpha \setminus \text{endpts}(\alpha) \) be the interior of \( \alpha \). We let \( \mathcal{A} \) be the set of simple arcs in \( \mathbb{R}^2 \). A planar embedding of \( G \) is a map \( g : V(G) \cup E(G) \to \mathbb{R}^2 \cup \mathcal{A} \) that assigns a point \( g(v) \in \mathbb{R}^2 \) to each vertex \( v \in V(G) \) and a simple arc \( g(\{ u, v \}) \in \mathcal{A} \) with each edge \( \{ u, v \} \) in such a way that the following conditions are satisfied.

1. For each \( u, v \in V(G) \), \( g(u) \neq g(v) \).
2. For each \( \{ u, v \} \in E(G) \), \( \{ g(u), g(v) \} \) are the endpoints of the simple arc \( g(\{ u, v \}) \).
3. For each \( \{ u, v \} \in E(G) \), and each \( w \in V(G) \) such that \( w \neq u \) and \( w \neq v \), \( g(w) \notin g(\{ u, v \}) \).
4. For each \( \{ u, v \}, \{ u', v' \} \in E(G) \), \( \text{Int}(g(\{ u, v \})) \cap \text{Int}(g(\{ u', v' \})) = \emptyset \).

Intuitively, a planar embedding of a graph \( G \) is a drawing of \( G \) on the plane where each vertex \( v \) is represented by a point and each edge \( e \) is represented by a non self-intersecting curve that connects the points corresponding to the endpoints of \( e \), and no crossings are allowed. A plane graph is a pair \( G^p = (G, g) \) where \( G \) is a graph and \( g \) is a planar embedding of \( G \). For technical reasons, in this work we assume that the origin \((0, 0) \in \mathbb{R}^2 \) is distinct from \( g(v) \) for each \( v \in V(G) \) and does not belong to \( g(e) \) for each edge \( e \in E(G) \).

**Plane Completion.** Let \( G \) and \( H \) be graphs. We say that \( G \) is a subgraph of \( H \) if \( V(G) \subseteq V(H) \) and \( E(G) \subseteq E(H) \). If \( G^p \) and \( H^p \) are plane graphs, then we say that \( G^p \) is a plane
subgraph of $H^h$ if $G$ is a subgraph of $H$, $g|_{V(G)} = h|_{V(G)}$ and $g|_{E(G)} = h|_{E(G)}$ \(^6\). Alternatively, we say that $H^h$ is a plane completion of $G^g$ (Figure 1). We say that such a completion $H^h$ is triangulated if each face of $H^h$ has three vertices.

**Combinatorial face.** Let $G^g$ be a plane graph. We say that a point $p \in \mathbb{R}^2$ is independent of $G^g$ if $p \neq g(v)$ for every $v \in V(G)$ and $p \notin g(e)$ for every $e \in E(G)$. We say that an independent point $p$ reaches a point $p' \in \mathbb{R}^2$ if there is a simple arc $\alpha$ with endpoints $p$ and $p'$ that does not contain any vertex in $g(V)\setminus \{p, p'\}$ and does not intersect the interior of any arc in $g(E)$. If $p$ is an independent point then we let $\mathcal{F}(G^g, p)$ be the subgraph of $G$ whose vertex set is $V(\mathcal{F}(G^g, p)) = \{v \in V(G) \mid p \text{ reaches } g(v)\}$ and whose edge set is $E(\mathcal{F}(G^g, p)) = \{e \in E(G) \mid p \text{ reaches each point in } g(e)\}$.

We let $b(p)$ be a boolean value that is 0 if the origin $(0,0)$ is reachable from $p$, and 1 otherwise. We say that a pair $F = (X, b)$, where $X$ is a subgraph of $G$ and $b \in \{0, 1\}$, is a combinatorial face if there exists a $p \in \mathbb{R}^2$ such that $X = \mathcal{F}(G^g, p)$ and $b = b(p)$. For instance, if $G^g$ is a plane graph where $G$ is a tree, then the unique combinatorial face of $G^g$ is the pair $F = (G, 1)$. On the other hand, if $G$ is a cycle, then $G^g$ has two faces: $F_1 = (G, 0)$ and $F_2 = (G, 1)$. We write $F(G^g)$ to denote the set of all faces of $G^g$. We note that $F(G^g)$ has $O(|V(G)|)$ faces. If $F = (X, b)$ is a combinatorial face, then we define $V(F) = V(X)$ and $E(F) = E(X)$.

We say that two embedded versions $G^g$ and $G^g'$ of a graph $G$ are equivalent if $F(G^g) = F(G^g')$. We write $G^g \equiv G^g'$ to denote that $G^g$ and $G^g'$ are equivalent.

### 3 Nooses

**Definition 3.** Let $G^g$ be a plane graph. A $G^g$-noose is a subset $\eta \subseteq \mathbb{R}^2$ homeomorphic to the unit circle $S_1$ such that $\eta \cap \text{Int}(g(\{u\})) = \emptyset$ for every edge $uv \in E(G)$.

We note that if $\eta$ is a $G^g$-noose, the intersection $\eta \cap g(V(G))$ may be non-empty. We let $V(\eta) = \{v \in V(G) \mid g(v) \in \eta\}$ be the set of vertices of $G$ whose image lies in the noose $\eta$. The size of $\eta$ is defined as $|\eta| = |V(\eta)|$.

![Figure 2](image1)

**Figure 2** Left: a plane graph $G$ and one of its nooses $\eta$. Right: the graph $G^g_{\eta}$ that lies in the interior of $\eta$.

\(^6\) Where $g|_{V(G)}$ and $g|_{E(G)}$ denote the restrictions of $g$ to $V(G)$ and to $E(G)$ respectively.
Embedded Planar Diameter Improvement

**Combinatorial cycle.** Let $\Sigma$ be a finite set. We let $\Sigma^k$ be the set of sequences of length $k$ over $\Sigma$. If $a_0a_1...a_{k-1}$ is a sequence in $\Sigma^k$, then we let

$$[a_0a_1...a_{k-1}] = \{a_{i_0}a_{j_1}...a_{j_{k-1}} \mid \exists l \in \{0,...,k-1\} \forall i \in \{0,...,k-1\}, j_i = i + l \mod k\}.$$ 

be the set of all cyclic shifts of the string $a_0a_1...a_{k-1}$. We say that the set $[a_0a_1...a_{k-1}]$ is a combinatorial cycle over $\Sigma$.

**Noose Type.** Let $G^\eta$ be a plane graph and $\Sigma(G) = V(G) \cup F(G)$. A $G^\eta$-noose type is a cycle $\tau = [v_0F_0v_1F_1...v_{r-1}F_{r-1}]$ over $\Sigma(G)$ where $\{v_0,...,v_{r-1}\} \subseteq V(G)$, $\{F_0,...,F_{r-1}\} \subseteq F(G^\eta)$, and $\{v_i,v_{i+1}\mod r\} \subseteq V(F_i)$ for each $i \in \{0,1,...,r-1\}$. We say that a $G^\eta$ noose $\eta$ is compatible with $\tau$ if there exist simple arcs $\ell_0,...,\ell_{r-1}$ satisfying the following properties.

1. $\eta = \bigcup_{i \in \{0,...,r-1\}} \ell_i$.
2. For each $i \in \{0,...,r-1\}$, $\text{endpts}(\ell_i) = \{g(v_i),g(v_{i+1} \mod r)\}$.
3. For each $i \in \{0,...,r-1\}$, $\ell_i \cap \ell_{i+1} \mod r = v_{i+1} \mod r$.

We say that two $G^\eta$-nooses $\eta_1$ and $\eta_2$ are equivalent if there exists a $G^\eta$-noose type $\tau$ such that both $\eta_1$ and $\eta_2$ are compatible with $\tau$. We note that uncountably many $G^\eta$-nooses may be compatible with a given $G^\eta$-noose type $\tau$.

![Figure 3](image-url) The type of the noose type $\eta$ is the cycle $[v_1F_2v_3v_4v_5v_6]$. Note that the segment of $\eta$ between $v_1$ and $v_3$ lies in the area delimited by the face $F_2$, the segment between $v_3$ and $v_5$ lies in the area delimited by face $F_1$ and so on.

Let $\gamma$ be a subset of $\mathbb{R}^2$ homeomorphic to the unit circle $S_1$. We say that a point $p \in \mathbb{R}^2$ belongs to the closed interior of $\gamma$ if $\alpha \cap \gamma \neq \emptyset$ for every simple arc $\alpha$ with $\text{endpts}(\alpha) = \{(0,0),p\}$. Let $\hat{\gamma}$ be the set of points in the closed interior of $\gamma$. If $G^\eta = (G,g)$ is a plane graph and $\eta$ is a $G^\eta$-noose, then we let $G^\eta_\eta = (G_\eta,g_\eta)$ be the plane graph where

1. $V(G_\eta) = \{v \in V(G) \mid g(v) \in \hat{\eta}\}$.
2. $E(G_\eta) = \{uv \in E(G) \mid g(uv) \subset \hat{\eta}\}$.
3. $g_\eta : V(G_\eta) \cup E(G_\eta) \to \mathbb{R}^2 \cup \mathcal{A}$ with $g_\eta|V(G_\eta) = g|V(G_\eta)$ and $g_\eta|E(G_\eta) = g|E(G_\eta)$.

Intuitively, the graph $G^\eta_\eta$ is the plane subgraph of $G^\eta$ that lies in the closed interior of $\eta$.

**Observation 1.** Let $G^\eta$ be a plane graph and $\eta_1$ and $\eta_2$ be equivalent $G^\eta$-nooses. Then $G^{\eta_1}_{\eta_1} = G^{\eta_2}_{\eta_2}$.

**Definition 4.** Let $G^\eta$ be a plane graph and $\tau$ be a $G^\eta$-noose type. We say that a plane completion $H^b$ of $G^\eta_\eta$ is $\tau$-respecting if there is a $G^\eta$-noose $\eta$ of type $\tau$ which is also a $H^b$-noose.

We note that in Definition 4, although the $G^\eta$-noose type of $\eta$ is $\tau$, the $H^b$-noose type of $\eta$ is not necessarily $\tau$ since $H^b$ may have more faces than $G^\eta$. 
4 Representative Sets

Let \( G^g \) be a plane graph and \( \eta \) be a \( G^g \)-noose. We say that a plane completion \( H^h \) of \( G^g \) is \( \eta \)-respecting if \( \eta \) is also an \( H^h \)-noose. We say that a plane graph \( X^x \) is a \((G^g, \eta)\)-completion if the following conditions are satisfied.

1. \( \eta \) is a \( X^x \)-noose.
2. \( X^x = X^x_\eta \).
3. \( X^x \) is a plane completion of \( G^g_\eta \).

Intuitively, a \((G^h, \eta)\)-completion is a plane completion \( X^x \) of \( G^h_\eta \) where all vertices and edges are drawn inside \( \eta \).

\( \triangleright \) **Proposition 1.** If \( H^h \) is an \( \eta \)-respecting plane completion of \( G^g \), then \( H^h_\eta \) is a \((G^g, \eta)\)-completion.

If \( G^g \) is a plane graph and \( H^h \) is a plane subgraph of \( G^g \) then we let \( G^g - H^h \) be the plane graph \( Y^y \) where \( V(Y) = V(G) \), \( E(Y) = E(G) \setminus E(H) \) and \( y = g|_{V(Y)} \). In other words, \( G^g - H^h \) is the graph obtained by deleting from \( G \) the edges which are shared with \( H \). On the other hand, let \( G^g \) and \( H^h \) be plane graphs such that \( V(H) \subseteq V(G) \), \( \text{Int}(h(e)) \cap g(e') = \emptyset \) for every \( e \in E(H) \setminus E(G) \) and every \( e' \in E(G) \), and such that \( h(e') = g(e) \) for every \( e \in E(G) \). We let \( G^g + H^h \) be the plane graph \( Y^y \) with vertex set \( V(Y) = V(G) \), edge set \( E(Y) = E(G) \cup E(H) \), and embedding \( y \) such that \( y|_{V(G)} = g|_{V(G)} \), \( y|_{E(G)} = g|_{E(G)} \) and \( y|_{E(H) \setminus E(G)} = h|_{E(H) \setminus E(G)} \). In other words, \( G^g + H^h \) is the graph obtained by adding all edges in \( E(H) \setminus E(G) \) to \( G \) and by drawing these edges in the plane according to \( h \).

We say that \( H^h \) is an \( \eta \)-respecting diameter-\( d \) plane completion of \( G^g \) if \( H^h \) is a \( \eta \)-respecting plane completion of \( G^g \) of diameter at most \( d \).

\( \triangleright \) **Definition 5.** Let \( G^g \) be a plane graph and \( \eta \) be a \( G^g \)-noose. Let \( A \) and \( B \) be sets of \((G^g, \eta)\)-completions. We say that \( A \) represents \( B \) if for every diameter-\( d \) \( \eta \)-respecting plane completion \( H^h \) of \( G^g \), such that \( H^h_\eta \subseteq B \), there exists some \( X^x \subseteq A \) such that \((H^h - H^h_\eta) + X^x \) is also a diameter-\( d \) plane completion of \( G^g \).

Let \( G^g \) be a plane graph and \( \eta \) be a \( G^g \)-noose. We let \( V(\eta) = \{ v \in V(G) \mid g(v) \in \eta \} \) be the set of vertices of \( G \) whose image under \( g \) lies on \( \eta \), and \( \hat{V}(\eta) \) be the set of vertices of \( G \) that lie in the closed interior of \( \eta \).

Let \( X^x \) be a \((G^g, \eta)\)-completion. The truncated distance between any two vertices \( v, v' \) of \( \hat{V}(\eta) \), denoted by \( d(X^x, v, v') \) is defined as the distance between \( v \) and \( v' \) in \( X^x \) if this distance is at most \( d \), and \( \infty \) otherwise. We let \( D(X^x) = [d(X^x, v, v')]_{v,v' \in \hat{V}(\eta)} \) be the matrix of truncated distances between any two vertices in \( \hat{V}(\eta) \). For any vertex \( v \) in \( \hat{V}(\eta) \), we let \( D(X^x, v) = [d(X^x, v, v')]_{v' \in \hat{V}(\eta)} \) be the vector of distances between \( v \) and the vertices whose image lie in the noose \( \eta \). We say that two vertices \( u \) and \( u' \) in \( \hat{V}(\eta) \) are unresolved if their distance in \( X^x \) is greater than \( d \). For each pair of unresolved vertices we let \( D(X^x, u, u') = \{D(X^x, u), D(X^x, u')\} \) be the pair of distance vectors from \( u \) to \( \hat{V}(\eta) \) and from \( u' \) to \( \hat{V}(\eta) \) respectively. We let

\[ \mathbb{D}(X^x) = \{D(X^x, u, u') \mid (u, u') \text{ is an unresolved pair}\}. \]

The signature of \( X^x \) is defined as follows.

\[ S(X^x) = (D(X^x), \mathbb{D}(X^x)). \] (1)

\( \triangleright \) **Proposition 2.** Let \( |V(\eta)| \leq 8d \). Then there exist at most \( 2^{d(D(\eta))} \) distinct signatures.
Lemma 6. Let \( H^b \) be a plane completion of \( G^9 \) of diameter at most \( d \) and let \( X^2 \) be a \((G^9, \eta)\)-completion such that \( S(H^b, \eta) = S(X^2, \eta) \). Then if \( H^9 \) has diameter at most \( d \), \((H^b - H^9) + X^2 \) has diameter at most \( d \).

Lemma 7. Let \( G^9 \) be a plane graph, \( \eta \) be a \((G^9, \tau)\)-noose and \( B \) be a set of \((G^9, \tau)\)-completions. Then one can construct in time \( 2^{d^O(d)} \cdot |B| \) a set \( \text{Trunc}(B) \) of \((G^9, h)\)-completions such that \( |\text{Trunc}(B)| \leq d^O(d) \) and \( \text{Trunc}(B) \) represents \( B \).

Proof. Let \( B \) be a set of \((G^9, \eta)\) completions. For each signature \( S \), let \( B(S) \) be the set of all graphs \( H^b \) in \( B \) with \( S(H^b, \eta) = S \). Finally, let \( \text{Trunc}(B) \) be the set obtained by selecting a unique graph \( H^b \) from set \( B(S) \) whenever \( B(S) \) is non-empty. Then by Lemma 6, \( \text{Trunc}(B) \) represents \( B \).

5 Algorithm for Embedded Planar Diameter Improvement

In this section we will devise an algorithm that takes a plane graph \( G^9 \) and a positive integer \( d \) as input and determines in time \( |V(G)|^{d^O(d)} \) whether \( G^9 \) has a diameter-\( d \) plane completion \( H^b \). In the reminder of this section we assume that the input plane graph \( G^9 \) and the input positive integer \( d \) are fixed.

Definition 8. Let \( \eta \) be a \( G^9 \)-noose. We define the following set.

\[ \mathcal{F}_\eta = \{ H^b \eta \mid H^b \text{ is a diameter-}d \text{ plane completion of } G^9 \} \]

Intuitively, \( \mathcal{F}_\eta \) is the set of all plane completions of the graph \( G^9_\eta \) that can be extended to some diameter-\( d \) plane completion of the graph \( G^9 \). For each \( G^9 \)-noose \( \eta \) we will define a family \( \tilde{\mathcal{F}}_\eta \subseteq \mathcal{F}_\eta \) of \((G^9, \eta)\)-completions such that \( \tilde{\mathcal{F}}_\eta \) represents \( \mathcal{F}_\eta \) and \( |\tilde{\mathcal{F}}_\eta| \leq 2^{d^O(d)} \).

We will define a partial order on nooses as follows. First, for each noose \( \eta \), we consider the following triple.

\[ \phi(\eta) = (|V(G^9_\eta)|, |E(G^9_\eta)|, -|\eta|) \]

We set \( \eta < \eta' \) if and only if \( \phi(\eta) < \phi(\eta') \). In other words, a noose \( \eta \) is smaller than a noose \( \eta' \) if the closed interior of \( \eta \) has less vertices than the closed interior of \( \eta' \), or if these interiors have the same number of vertices, but the first has less edges, or if both interiors have the same number of edges and vertices and the first noose has more vertices than the latter noose. Note that there is an inversion in the third coordinate, since the larger the noose-size, the lesser is the order.

We will compute \( \tilde{\mathcal{F}}_\eta \) under the assumption that \( \tilde{\mathcal{F}}_{\eta'} \) has been computed for every \( \eta' \) such that \( \phi(\eta') < \phi(\eta) \). There are three cases to be considered. In all cases the size of the involved nooses will be at most \( 8d \). In the first case, assuming that the size of \( \eta \) is at most \( 8d \), we will show how to compute \( \tilde{\mathcal{F}}_\eta \) under the assumption that \( \tilde{\mathcal{F}}_{\eta'} \) has been computed for every noose \( \eta' \) whose closed interior has fewer edges than the one of \( \eta \). The second case concerns nooses of size strictly less than \( 8d \). In this case, we will show how to compute \( \tilde{\mathcal{F}}_{\eta'} \) assuming that we have computed \( \tilde{\mathcal{F}}_{\eta'} \) for every noose \( \eta' \) of size \( |\eta| + 1 \) whose closed interior is identical to the one of \( \eta \). Note that due to the negative sign in the definition of \( \phi(\eta) \), if two nooses \( \eta \) and \( \eta' \) have identical closed interior and \( |\eta'| > |\eta| \), then \( \phi(\eta') < \phi(\eta) \). Finally, the most important case is the third, in which nooses have size exactly \( 8d \). In this case we show how to compute \( \tilde{\mathcal{F}}_\eta \) assuming we have computed \( \tilde{\mathcal{F}}_{\eta'} \) for every noose of size \( 8d \) whose closed interior is strictly contained in the closed interior of \( \eta \). We note that we only need to consider one noose \( \eta' \) for each noose-type \( \tau \). Therefore, the number of nooses to be considered will be upper bounded by \( n^{O(\eta)} \).
Case One. Let $G^\eta$ be a plane graph and $\eta$ be a $G^\eta$-noose with $|\eta| < 8d$. We say that an edge $uv \in E(G)$ is parallel to $\eta$ if there exists a simple arc $\ell \in \mathcal{A}$ such that the following conditions are satisfied.
1. $\ell \subseteq \eta$.
2. $\text{endpts}(\ell) = \{g(u), g(v)\}$.
3. Let $\alpha = \ell \cup g(uv)$ and let $\hat{\alpha}$ be the closed interior of $\alpha$.
   a. $\hat{\alpha} \cap g(V(G)) = \{g(u), g(v)\}$.
   b. $\hat{\alpha} \cap g(u'v') \subseteq \{g(u), g(v)\}$ for each $u'v' \in E(G)$.

In other words, $uv$ is parallel to $\eta$ if there is a simple arc $\ell \subset \eta$ with endpoints $\{g(u), g(v)\}$ such that the closed interior of the curve $\ell \cup g(uv)$ only intersects the drawing of $G$ in the points of $g(u, v)$ (Figure 4).

We say that an edge $uv \in E(G)$ is internally (resp. externally) parallel to $\eta$ if $uv$ is parallel to $\eta$ and $g(uv) \subset \eta$ (resp. $g(uv) \cap \eta = \{g(u), g(v)\}$). We note that if an edge $uv$ is parallel to $\eta$, then $uv$ is either internally or externally parallel to $\eta$. Let $G^\eta$ be a plane graph and $uv \in E(G)$. We let $G^\eta - uv$ be the plane graph which is obtained by deleting the edge $uv$ from $E(G)$ and by restricting the mapping $g$ to the remaining edges.

> Proposition 3. Let $\eta$ be a $G^\eta$-noose, and let $uv$ be an edge in $E(G)$ such that $uv$ is internally parallel to $\eta$. Then there exists a $G^\eta$-noose $\eta'$ such that $V(\eta) = V(\eta')$, $uv$ is externally parallel to $\eta'$ and $G^{\eta'}_{\eta'} = G^{\eta}_{\eta} - uv$. (See Figure 4).

![Figure 4](https://example.com/figure4.png)

The edge $uv$ is internally parallel to $\eta$ and externally parallel to $\eta'$. Note that the graph $G^{\eta'}_{\eta'}$ is equal to the graph $G^{\eta}_{\eta}$ minus the edge $uv$. Intuitively, the noose $\eta'$ is obtained from $\eta$ by deleting the arc $\ell$ and by gluing the arc $\ell'$ in its place.

> Lemma 9. Let $uv$ be an edge in $E(G)$, and let $\eta$ be a $G^\eta$-noose such that $uv$ is internally parallel to $\eta$. Let $\eta'$ be a $G^\eta$-noose such that $V(\eta) = V(\eta')$, $G^{\eta'}_{\eta'} = G^{\eta}_{\eta} - uv$ and $uv$ is externally parallel to $\eta'$. Note that such a noose $\eta'$ exists by Proposition 3. Suppose that $X^x \in \mathcal{F}_\eta$. Then there exists $Y^y \in \mathcal{F}_{\eta'}$ such that $Y^y = X^x - uv$.

Let $Y^y$ be a $(G^\eta, \eta)$-completion and $uv$ be an edge in $E(G) \setminus E(Y)$ such that $u, v \in V(\eta)$. We let $Y^y + uv$ be the plane graph $X^x$ where $V(X) = V(Y)$, $E(X) = E(Y)$, $x|_{V(G)\cup E(G)} = y$ and $x(uv) = g(uv)$.

> Lemma 10. Let $uv$ be an edge in $E(G)$, and let $\eta$ and $\eta'$ be $G^\eta$-nooses such that $V(\eta) = V(\eta')$ and $G^\eta_{\eta'} = G^\eta_{\eta} + uv$. Assume that $\hat{\mathcal{F}}_{\eta'}$ represents $\mathcal{F}_{\eta'}$. Then $\hat{\mathcal{F}}_{\eta} = \hat{\mathcal{F}}_{\eta'} + uv$ represents $\mathcal{F}_{\eta}$.

Case Two. Let $k < 8d$ and let $\eta$ be a $G^\eta$-noose of type $\tau = [v_0F_0v_1F_1...v_{k-1}F_{k-1}]$. A trivial extension of $\eta$ is a noose $G^\eta$-noose $\eta'$ of type $\tau = [v_0F_0v_1F_1...v_jF_juF_jv_{j+1}...v_{k-1}F_{k-1}]$.
We let $\eta$ apply the maximal with respect to length. In this section we will deal with the case in which $\ell$ arcs $\tau$ sequences. Lemma 12. Let $\eta$ be an extensible noose. Suppose that $\hat{F}_\eta$ represents $F_\eta'$ for every $\eta' \in \text{Ext}(\eta)$. Then $\hat{F}_\eta$ represents $F_\eta$.

Note that the number of extensions of a noose $\eta$ may be linear in $|V(G)|$. Therefore, the number of plane graphs in $\hat{F}_\eta$ may be linear in $|V(G)|$. To decrease the size of this family, we apply the $\text{Trunc}$ operator introduced in Section 4.

Lemma 12. Let $\eta$ be an extensible noose and let $\hat{F}_\eta = \text{Trunc}(\hat{F}_\eta)$. Then $\hat{F}_\eta$ represents $\mathcal{F}_\eta$.

Case Three. In this section we will deal with the case in which $|\eta| = 8d$. Let $G^g$ be a plane graph. A face-vertex sequence is a sequence $X = F_1v_1F_2...v_{r-1}F_r$ where $r \geq 1$, $\{v_1, ..., v_{r-1}\} \subseteq V(G)$, $\{F_1, ..., F_r\} \subseteq F(G)$, and for each $i \in \{1, ..., r - 2\}$, $v_i$ and $v_{i+1}$ are in $F_i$. We note that any noose type $\tau = [v_0F_0v_1...v_mF_m]$ where $m \geq 1$ can be written as $\tau = [v_0Xv_1Y]$ where $X = F_1v_1F_2...v_{r-1}F_{r-1}$ and $Y = F_rv_{r+1}F_{r+1}...v_mF_m$ are face-vertex sequences.

The reverse of a face-vertex sequence $X = F_1v_1F_2...v_{r-1}F_r$ is the face-vertex sequence $X^R = F_rv_{r-1}...F_2v_1F_1$. Let $\tau_1$ and $\tau_2$ be noose types. We say that $\tau_1$ and $\tau_2$ are summable if there is a unique maximal face-vertex sequence $X = X(\tau_1, \tau_2)$ with the property that there exist vertices $v, v'$ and face-vertex sequences $Y$ and $Z$ such that $\tau_1 = [vYv'X]$ and $\tau_2 = [v'ZvX^R]$. If this is the case, the sum of $\tau_1$ and $\tau_2$ is defined as $\tau_1 \oplus \tau_2 = [vYv'Z]$. We let $V(X(\tau_1, \tau_2))$ denote the vertices which lie in the face vertex sequence $X(\tau_1, \tau_2)$.

We note that a noose $\eta$ has type $\tau_1 \oplus \tau_2$ if and only if there exist vertices $v, v'$ and simple arcs $\ell_1, \ell_1', \ell_2, \ell_2'$ with endpoints $\{v, v'\}$ satisfying the following properties.

1. $\ell_1 \cap \ell_1' = \ell_2 \cap \ell_2' = \ell_1 \cap \ell_2 = \{v, v'\}$.
2. $g(V(X(\tau_1, \tau_2))) \subseteq \ell_1' \cap \ell_2'$.
3. $\eta = \ell_1 \cup \ell_2$.
4. $\eta_1 = \ell_1 \cup \ell_1'$ is a noose of type $\tau_1$.
5. $\eta_2 = \ell_2 \cup \ell_2'$ is a noose of type $\tau_2$.

Intuitively, $\eta$ is obtained from $\eta_1$ and $\eta_2$ by the following process. First, we delete the interior of $\ell_1'$ from $\eta_1$ to obtain the segment $\ell_1$, and we delete the interior of $\ell_2'$ from $\eta_2$ to

---

7 Maximal with respect to length.
obtain the segment $\ell_2$. Subsequently, we glue $\ell_1$ with $\ell_2$ along their common endpoints in order to obtain the noose $\eta$. We note that if $\eta = \eta_1 \oplus \eta_2$ then $G^\eta_{\eta_1} = G^\eta_{\eta_1} \cup G^\eta_{\eta_2}$.

Let $\eta$ be a $G^\eta$-noose with $|\eta| = 8d$ and let $H^h_\eta$ be a triangulated $\eta$-respecting diameter-$d$ plane completion of $G^\eta$. Let $V_1 \cup V_2 \cup V_3 \cup V_4$ be a partition of $V(\eta)$ where for each $i \in \{1, 2, 3, 4\}$, $V_i$ has $d$ consecutive vertices. Let $\hat{V}_1 \cup \hat{V}_2 \cup \hat{V}_3 \cup \hat{V}_4$ be a partition of the vertex set of $H^h_\eta$ where for each $v \in V(\eta^{h_\eta})$,

$$v \in \hat{V}_i \iff \left[ \text{dist}(v, V_i) < \min_{j<i} \text{dist}(v, V_j) \land \text{dist}(v, V_i) \leq \min_{j>i} \text{dist}(v, V_j) \right].$$

Intuitively, the set of vertices incident with the noose $\eta$ is partitioned into four consecutive sections of size $d$: north ($V_1$), east ($V_2$), south ($V_3$) and west ($V_4$). Subsequently, each vertex $v \in V(G^\eta_{\eta})$ is classified as being north ($\hat{V}_1$), east ($\hat{V}_2$), south ($\hat{V}_3$) or west ($\hat{V}_4$) according to whether $v$ is closer to a northern, eastern, southern or western vertex from the noose. In the case in which a vertex $v$ is as close to $V_i$ as it is to $V_j$, for some $i \neq j$, ties are broken by considering that north is smaller than east, which is smaller than south, which is smaller than west. We note that the way in which we have decided to break ties is completely arbitrary.

▸ **Lemma 13.** There is an edge $uv \in E(H^{h_\eta}_{\eta})$ such that either $u \in \hat{V}_1$ and $v \in \hat{V}_3$, or $u \in \hat{V}_2$ and $v \in \hat{V}_4$.

▸ **Lemma 14.** At least one of the following statements must be satisfied.
1. There is a path of length at most $2d + 1$ between a vertex in $V_1$ to a vertex in $V_3$.
2. There is a path of length at most $2d + 1$ between a vertex in $V_2$ and a vertex in $V_4$.

![Figure 6](image_url) Left: A noose $\eta$ with $8d$ vertices, and the sets $V_i$ and $\hat{V}_i$. Either there is an edge from a maximal element of $\hat{V}_1$ to a maximal element of $\hat{V}_3$, or an edge between a maximal element of $V_2$ and a maximal element of $\hat{V}_4$. Middle: A path from $V_5$ to $V_3$ is depicted. Right: the path from $V_5$ to $V_3$ can be used to show that $\eta = \eta_1 \oplus \eta_2$ for nooses $\eta_1$ and $\eta_2$ where can be split into nooses $\eta_1 \oplus \eta_2$.

▸ **Lemma 15.** Let $H^h_\eta$ be a $\eta$-respecting diameter-$d$ plane triangulated completion of $G^\eta$.
Then there exist $G^\eta$-nooses $\eta_1$ and $\eta_2$ satisfying the following properties.
1. $|V(\eta_1)| \leq 8d$ and $|V(\eta_2)| \leq 8d$.
2. $\eta = \eta_1 \oplus \eta_2$.
3. $H^h_\eta$ is both $\eta_1$-respecting and $\eta_2$-respecting.
4. $H^{h_{\eta_1}}_{\eta_1} = H^{h_{\eta_2}}_{\eta_2}$.

Let $\eta$, $\eta_1$ and $\eta_2$ be $G^\eta$ nooses such that $\eta = \eta_1 \oplus \eta_2$. Then we define the following set:

$$F_{\eta_1} \oplus F_{\eta_2} = \{ X^x \cup Y^y \mid X^x \in F_{\eta_1}, Y^y \in F_{\eta_2} \}.$$ Then, Lemma 15 implies that whenever $|\eta| = 8d$, $F_\eta = \bigcup_{\eta = \eta_1 \oplus \eta_2} F_{\eta_1} \oplus F_{\eta_2}$. 

**Lemma 16.** Let \( \eta \) be a \( G^d \)-noose with \( |\eta| = 8d \), and assume that for every two \( G^d \)-nooses \( \eta_1 \) and \( \eta_2 \) such that \( \eta = \eta_1 \oplus \eta_2 \) we have that \( \tilde{F}_{\eta_1} \) represents \( F_{\eta_1} \), and \( \tilde{F}_{\eta_2} \) represents \( F_{\eta_2} \). Then \( F_{\eta} \) is represented by the following set.

\[
\tilde{F}_{\eta} = \text{Trunc} \left( \bigcup_{\eta = \eta_1 \oplus \eta_2} \tilde{F}_{\eta_1} \oplus \tilde{F}_{\eta_2} \right) = \text{Trunc} \left( \bigcup_{\eta = \eta_1 \oplus \eta_2} \{ X^x \cup Y^y \mid X^x \in \tilde{F}_{\eta_1}, Y^y \in \tilde{F}_{\eta_2} \} \right)
\]

**Algorithm.** Now we summarize our algorithm for determining whether a given plane graph \( G^d \) admits a plane completion of diameter at most \( d \). We assume that the graph has at least \( d \) vertices, since otherwise the graph has trivially a completion of diameter at most \( d \). As a first step we enumerate all combinatorial faces of \( G^d \), constructing in this way the set \( F(G^d) \). We note that there exists at most \( O(|V(G)|) \) such faces, and the set \( F(G^d) \) can clearly be constructed in time \( |V(G)|O(1) \). As a second step, we enumerate all noose types containing at most \( 8d \) vertices. In other words, we enumerate all cycles \( \tau = [v_0 F_1 v_1 ... v_{\tau-1} F_{\tau}] \) where \( \tau - 1 \leq 8d \), and verify if \( \tau \) is a valid noose type. Since there are at most \( O(|V(G)|) \) combinatorial faces, there are at most \( |V(G)|O(d) \) possible noose types with at most \( 8d \) vertices. Let \( T \) be the set of all such noose types. Now, for each noose type \( \tau \in T \), we select an arbitrary noose \( \eta_\tau \) of type \( \tau \). We say that \( \eta_\tau \) is a representative for \( \tau \). Let \( \mathcal{N} = \{ \eta_\tau \}_{\tau \in T} \) be the set of all such nooses.

For each noose \( \eta \in \mathcal{N} \), we will compute a set \( \tilde{F}_{\eta} \) containing at most \( 2^{dO(d)} \) triangulated plane completions of the graph \( G^d_{\eta} \). In particular the set \( \tilde{F}_{\eta} \) represents the set \( F_{\eta} \). The sets \( \tilde{F}_{\eta} \) are computed by dynamic programming.

In the base case, let \( \mathcal{N}^0 \subseteq \mathcal{N} \) be the minimal elements of \( \mathcal{N} \) with respect to the noose ordering defined in the beginning of Section 5. For each such minimal noose \( \eta^0 \), we have that \( |V(\eta^0)| = 3 \), and the graph \( G^d_{\eta^0} \) has no edges. Therefore the set \( \tilde{F}_{\eta^0} \) can be constructed in constant time in this case.

Now assume that we are dealing with a non-minimal noose \( \eta \in \mathcal{N} \) and that \( \tilde{F}_{\eta'} \) has been constructed for every \( \eta' < \eta \). We will show how to construct \( \tilde{F}_{\eta} \). There are three cases to be considered.

1. If there is some edge \( uv \in E(G) \) which is externally parallel to \( \eta \), then we consider a noose \( \eta' \) such that \( G^d_{\eta'} = G^d_{\eta} - uv \). Then we set \( \tilde{F}_{\eta} = \tilde{F}_{\eta'} + uv \).

2. If \( \eta \) is trivially extensible, then we let \( \tilde{F}_{\eta} = \text{Trunc} \left( \bigcup_{\eta' \in \text{Ext}(\eta)} \tilde{F}(\eta') \right) \).

3. If \( |\eta| = 8d \), then we let \( \tilde{F}_{\eta} = \text{Trunc} \left( \bigcup_{\eta = \eta_1 \oplus \eta_2} \tilde{F}_{\eta_1} \oplus \tilde{F}_{\eta_2} \right) \).

Now let \( \eta \) be a maximal noose in \( \mathcal{N} \). Then we have that \( |\eta| = 3 \) and that the graph \( G^d_{\eta} = G^d \). Therefore, we have that \( G^d \) admits a diameter-\( d \) plane completion if and only if the set \( \tilde{F}_{\eta} \) is non-empty. Additionally, if this is the case, then any graph in \( \tilde{F}_{\eta} \) is a diameter-\( d \) plane completion of \( G^d \).

Note that in any of the three cases above the time necessary to construct the set \( \tilde{F}_{\eta} \) from previously computed \( \tilde{F}_{\eta'} \) is at most \( 2^{dO(d)} \cdot |V(G)|O(d) \), since there are at most \( |V(G)|O(d) \) nooses in \( \mathcal{N} \) and each \( \tilde{F}_{\eta} \) has at most \( 2^{dO(d)} \) elements. This implies that the computation of \( \tilde{F}_{\eta} \) for every \( \eta \in \mathcal{N} \) also takes time at most \( 2^{dO(d)} \cdot |V(G)|O(d) \), as stated in Theorem 1.

**k-Outerplanar Plane Diameter Improvement.** The algorithm for solving the embedded \( k \)-outerplanar diameter improvement problem is almost identical to the one to solve the embedded planar diameter improvement problem. The only difference is that, since the input graph is \( k \)-outerplanar, we only need to consider nooses of size at most \( 8k \), instead of \( 8d \) as in the previous algorithm.
In particular, the proof of Lemma 14 may be adapted in such a way that if we split the set \( V(\eta) \) into sets \( V_1, V_2, V_3, V_4 \) as done previously, then there is either a path of length at most \( 2k \) between some vertex in \( V_1 \) and some vertex in \( V_3 \), or a path of length at most \( 2k \) between some vertex in \( V_3 \) and some vertex in \( V_4 \). As a consequence, the value \( 8d \) in Lemma 15 may be replaced with \( 8k \) when considering \( k \)-outerplanar graphs. With these adaptations our algorithm for the embedded \( k \)-outerplanar diameter improvement problem is guaranteed to run in time \( 2^{O(d)} \cdot |V(G)|^{O(k)} \) as stated in Theorem 2.
