Abstract

We present the web portal Λ-symsym, available at http://158.110.146.197:31780/automata/, for experimenting with game semantics of λ-calculus, and its normalizing elementary sub-calculus, the λEAL-calculus. The λ-calculus is a generalization of the λ-calculus obtained by introducing a modal operator !, giving rise to a pattern β-reduction. Its sub-calculus corresponds to an applicatively closed class of terms normalizing in an elementary number of steps, in which all elementary functions can be encoded. The game model which we consider is the Geometry of Interaction model I introduced by Abramsky to study reversible computations, consisting of partial involutions over a very simple language of moves.

Given a λ or a λEAL-term, M, Λ-symsym provides:
- an abstraction algorithm A!, for compiling M into a term, A' (M), of the linear combinatory logic CL!, or the normalizing combinatory logic CLEAL;
- an interpretation algorithm [ ]I yielding a specification of the partial involution [A' (M)]I in the model I;
- an algorithm, T2T, for synthesizing from [A' (M)]I a type, T2T([A' (M)]I), in a multimodal, intersection type assignment discipline, ⊢;
- an algorithm, T2I, for synthesizing a specification of a partial involution from a type in ⊢, which is an inverse to the former.

We conjecture that ⊢ M : T2T([A' (M)]I). Λ-symsym permits to investigate experimentally the fine structure of I, and hence the game semantics of the λI- and λEAL-calculi. For instance, we can easily verify that the model I is a λI-algebra in the case of strictly linear λ-terms, by checking all the necessary equations, and find counterexamples in the general case.

We make this tool available for readers interested to play with games (-semantics). The paper builds on earlier work by the authors, the type system being an improvement.

1 Introduction

We present the web portal Λ-symsym, available at http://158.110.146.197:31780/automata/, for experimenting, in the spirit of [24], with the game semantics of the λI-calculus, and its normalizing elementary affine sub-calculus, the λEAL-calculus. The λI-calculus is a generalization of the λ-calculus obtained by introducing a co-monadic modal operator !, which gives rise to a pattern β-reduction. Its sub-calculus corresponds to an applicatively closed class of terms normalizing in an elementary number of steps. All elementary functions
A-Symsym

can be encoded in the $\lambda^{EAL}$-calculus, cf [20, 6]. The game model that we consider consists of partial involutions, i.e. partial symmetric functions. These were introduced by Abramsky in [3] to provide a Geometry of Interaction model, $\mathcal{I}$, of reversible computation for linear combinatory logic, see also [4, 5].

In a series of papers by the authors, [12, 10, 11, 18], we have explored and extended Abramsky’s model $\mathcal{I}$. In particular, we have introduced:

- a generalized co-monadic $\lambda$-calculus, the $\lambda^1$-calculus, which subsumes also the elementary affine and linear affine calculi [26, 7, 6, 15, 16];
- abstraction algorithms for compiling the above calculi in corresponding fragments of an extended linear combinatory logic, CL$^I$ or the normalizing CL$^{EAL}$;
- a semantics of these combinatory logics in terms of partial involutions, and hence a semantics of the $\lambda^1$-calculus via the abstraction algorithm;
- a multi-modal intersection type systems $\vdash_1$ for the $\lambda^1$-calculus;
- an algorithm $TIT^I$ for obtaining a specification of a partial involution, given a type in the language of $\vdash_1$, and an algorithm $TIT^T$ for synthesizing a type given a specification of a partial involution, which are “morally” mutual inverses.

Moreover, we have shown that linear application between involutions, i.e. the game analogue of Girard’s “Execution Formula”, amounts to a kind of resolution between types in $\vdash_1$. In particular, in the case of strictly linear terms $M, N$, we have that $TIT^T([MN]^2) = TIT^I([M]^2 \cdot [N]^2) = RES(TIT^I([M]^2), TIT^I([N]^2))$, [12]. In this perspective, types deriving from $TIT^T$ can be viewed as a kind of principal types for terms in the $\lambda^1$-calculus.

In this paper, we outline the implementation of the algorithms above and present the online tool A-symsym\(^1\) for experimenting with them in a user-friendly interactive setting, thus allowing for the investigation of the fine structure and the peculiarities of the symmetric game semantics of $\lambda^1$-calculus. The sheer combinatorial complexity of applying linear application by hand, in effect, makes it essential to use a machine for checking equalities and finding counterexamples.

\textbf{A-symsym} easily provides evidence for the following facts.

- The model $\mathcal{I}$ of partial involutions does not satisfy any form of the $\xi$-rule, if the terms involved are not strictly linear. Namely, we can check all the necessary equations for $\mathcal{I}$ to be a $\lambda^1$-algebra in the strictly linear case and provide counterexamples otherwise.
- Partial involutions keep track of the history of the execution, such as the erasures of arguments or the comonad $!$.

In particular, given a normalizing $\lambda^1$-term, or a $\lambda^{EAL}$-term, $M$, the web tool provides a web application for compiling $M$ into a term of linear combinatory logic, $\Lambda'$($M$) or $\Lambda^{EAL}$($M$), respectively. Another web application provides the interpretation of $\Lambda'$($M$) as a specification, $[\Lambda'($$M$)$]^2$, of a partial involution over a very simple language of moves, in the model $\mathcal{I}$ of [3]. Yet another application permits to synthesize from $[\Lambda'($$M$)$]^2$ a type, $TIT^T([\Lambda'($$M$)$]^2)$, in a multimodal, intersection type discipline. The type assignment system is given in the form of a general type system $\vdash_1$, for which we conjecture that $\vdash_1 M : TIT^T([\Lambda'($$M$)$]^2)$. In this paper we do not discuss the other web applications made available by the tool A-symsym for dealing with the other $\lambda^1$-calculi of [18], and non normalizing terms.

We wrote this paper to encourage interested readers to enjoy utilizing A-symsym. We made it available for people to play with games (-semantics)!\(^2\)

\(^1\) We combine $\Lambda$ to the magic word of the formula Open Sesame, افتح يا حسم (iftah ya simsim), in the Arab collection of novels 1001 Nights, Autodesk sym is sym, which reminds that our semantics are symmetric partial functions.
Synopsis. In Section 2, we introduce in a self-contained format the formal systems used in the web tool, namely the $\lambda^!$-calculus, and the $\lambda^{EAL}$-calculus, the linear combinatory logics $CL^!$ and $CL^{EAL}$, $!$-intersection-types, and the $\uparrow_1$ type discipline. In Subsection 2.1 we give the corresponding abstraction algorithms. In Section 3, we present the game theoretic semantics of the linear combinatory logic $CL^!$, and hence of its normalizing sublogic $CL^{EAL}$, in terms of partial involutions. We introduce also the crucial concept of specification of an involution. In Subsection 3.1, we present the two algorithms $\mathcal{I}2\mathcal{T}$ and $\mathcal{T}2\mathcal{I}$, for mapping specifications of partial involutions into types and back. In Section 4, we illustrate the web tool A-sym.sym and present its web interface. In Subsection 4.2 we discuss remarkable example sessions. Finally, in Section 5, we draw some conclusions and outline future directions. In the Appendix A, we give the Erlang code corresponding to the implementation of linear application of involutions. The complete code of our web tool is available in [13].

2 The $\lambda^!$-calculus, Linear Combinatory Logic, $!$-intersection-types

In this section we recall the formal systems used in the web tool. Most of these appear already in earlier papers by the authors, see [12, 10, 11, 18], but for the definition of the type assignment system $\uparrow_1$.

We start with the $\lambda^!$-calculus and its sub-calculus.

Definition 1 ($\lambda^!$-calculus, $\lambda^{EAL}$-calculus).

The language $\Lambda^!$ of the $\lambda^!$-calculus is inductively defined from variables $x, y, z, \ldots$ and constants $c, \ldots$, and it is closed under the following formation rules:

- $M \in \Lambda^!$ $N \in \Lambda^!$ $\frac{\text{M.N} \in \Lambda^!}{(\text{app})}$
- $M \in \Lambda^!$ $\frac{!M \in \Lambda}{(!)}$
- $M \in \Lambda^!$ $O^1_{\geq 1}(x, M)$ $\frac{\lambda x. M \in \Lambda^!}{(\lambda)}$
- $M \in \Lambda^!$ $O^1_{\geq 1}(x, M)$ $\frac{\lambda x. M \in \Lambda^!}{(!)}$

where $FV(M)$ denotes the set of free variables of $M$, and $O^1_{\geq 1}(x, M)$ ($O^1_1(M)$), for $\#$ denoting either $!$ or blank, and $?$ denoting $\leq 1$ or $\geq 1$ or no constraint, means that the variable $x$ (the free variables of $M$) appears at most once ($\leq 1$) or at least once ($\geq 1$) in $M$, respectively, and, when $\#$ is not blank, that it cannot appear in the scope of $!$.

We denote by $\equiv$ syntactical identity on $\lambda$-terms.

The language $\Lambda^{EAL}$ of the $\lambda^{EAL}$-calculus is the restriction of $\Lambda^!$ obtained by considering rules (app), $(\lambda)$, and the following versions of the rules ($\beta$) and (!):

- $M \in \Lambda^{EAL}$ $O^1_{\geq 1}(x, M)$ $\frac{x \text{ is in the scope of a single !}}{\lambda x. M \in \Lambda^{EAL}}$
- $M \in \Lambda^{EAL}$ $O^1(M)$ $\frac{!M \in \Lambda^{EAL}}{(!)}$

The reduction rules of the $\lambda^!$-calculus include the restrictions of the standard ($\beta$)-rule and ($\xi$)-rule to linear abstractions, the pattern-$\beta$-reduction rule, which define the behaviour of the $!$ pattern abstraction operator, the corresponding (str!) structural rule, and the ($\xi!$) rule, namely:

- ($\beta$) $\frac{(\lambda x. M)N \rightarrow M[N/x]}{(\beta!)}$
- ($\xi$) $\frac{M \rightarrow N \lambda x. M \in \Lambda^!}{\lambda x. M \rightarrow N \lambda x. N}$
- ($\xi!$) $\frac{M \rightarrow N \lambda x. M \in \Lambda^!}{\lambda x. M \rightarrow !M \rightarrow N}$
- (appl)$\frac{M_1 \rightarrow M'_1}{M_1M_2 \rightarrow M'_1M_2}$
- (appl)$\frac{M_2 \rightarrow M'_2}{M_1M_2 \rightarrow M_1M'_2}$

We denote by $\rightarrow^*_\Rightarrow$ the reflexive and transitive closure of $\rightarrow_\Rightarrow$.

The reduction rules of the $\lambda^{EAL}$-calculus are the restrictions of the rules of the $\lambda^!$-calculus to $\Lambda^{EAL}$-terms. We denote by $\rightarrow_{EAL}$ the corresponding reduction relation.
We define strong normal forms as the irreducible terms which do not contain stuck redexes, i.e. subterms of the shape \((!M)N\) or \((\lambda x.M)P\), where P is irreducible and not a !-term.

**Definition 2 (Strong Normal Forms).** The set \(SN^1\) of strong normal forms is inductively defined as follows:

\[
\begin{align*}
M &\in SN^1 \quad \forall i \in \{1, \ldots, n\} \\
xM_1, \ldots, x_n &\in SN^1 \\
\lambda x.M &\in \Lambda^I
\end{align*}
\]

Of course many terms containing stuck redexes are typable in the typing system of Definition 6 below, and receive the appropriate involution semantics, e.g. \(\lambda x.(\lambda y.y)x\) behaves as \(\lambda!x.x\), but these intricacies are not worthwhile considering for the purposes of this paper.

The involution semantics of terms in \(\Lambda^I\) and in \(\Lambda^{EAL}\) will be given via a compilation in linear combinatory logic.

**Definition 3 (Linear Combinatory Logics).**

- The language of the extended linear combinatory logic \(CL^1\) consists of variables \(x, y, \ldots\), distinguished constants (combinators) \(B, C, I, K, W, D, \delta, F\), and it is closed under application and \(!\)-promotion, i.e.:

\[
\begin{align*}
M &\in CL^1 \quad N \in CL^1 \\
MN &\in CL^1 \\
!M &\in CL^1
\end{align*}
\]

In \(CL^1\)-terms, we associate \(\cdot\) to the left and we assume \(!\) to have order of precedence greater than \(\cdot\). Combinators reduce according to the following pattern reduction rules:

\[
\begin{align*}
BMNP &\rightarrow M(NP) \\
IM &\rightarrow M \\
CMNP &\rightarrow (MP)N \\
KMN &\rightarrow M \\
WM!N &\rightarrow M!N!N \\
\delta M &\rightarrow !!M \\
D!M &\rightarrow M \\
P!M!N &\rightarrow !(MN)
\end{align*}
\]

\[
\frac{M \rightarrow M'}{C[M] \rightarrow C[M']}, \text{ for any context } C[\ ].
\]

where one-hole contexts are defined as usual.

- The language of elementary affine combinatory logic \(CL^{EAL}\) includes only the combinators \(B, I, C, K, W, F\), and is closed under the rules of application and \(!\)-promotion. The reduction relation restricted to \(CL^{EAL}\) is denoted by \(\rightarrow^{EAL}\).

We use the notation \(Comb\) to denote any of the combinators in the above definition.

We recall the following proposition because it is not so immediate:

**Proposition 4 (Normalization [18]).** The \(\lambda^{EAL}\)-calculus and \(CL^{EAL}\) linear combinatory logic are strongly normalizing.

The type discipline introduced in this section is a refinement of the ones introduced in [10, 12, 11] and originated in the process of relating partial involutions and principal types. It amounts essentially to a multimodal intersection type discipline, which generalizes [8].

**Definition 5 (Type Language).** The language of types, \(Type^1\), is a two sorted language given by the following grammars, where \(\omega\) is a constant, and \(\alpha, \beta, \ldots, i, j, \ldots\) are type and index variables respectively:

\[
\begin{align*}
(Type^1 \triangleright) \quad &\sigma, \tau ::= \omega \mid \alpha \mid \ldots \mid \sigma \neg \tau \mid \hat{\sigma} \\
(Type^1 \triangleright) \quad &\hat{\sigma}, \hat{\tau} ::= !\sigma \mid \hat{\sigma} \land \hat{\tau} \\
u, v ::= \epsilon \mid i \mid j \mid \ldots \mid (u, v).
\end{align*}
\]

The syntactic category \(\hat{\sigma}\)-types isolates types whose main constructor is \(!\) or \(\land\). Moreover, we consider the equivalence relation on types \(\sim\) induced by \(\omega \sim \sigma\), for any type \(\sigma\) which contains only the constant \(\omega\) and no type variables.
Definition 6 (Type System).
The type system \( \Gamma \vdash \) derives judgements \( \Gamma \vdash M : \tau \), where the environment \( \Gamma \) is a set of pairs of the following shapes: \( x : \sigma, !x : \tilde{\sigma} \); each variable occurs at most once in \( \Gamma \) either as a linear variable or a \( ! \)-variable. \( \text{dom}(\Gamma) \) denotes the set of variables which appear in \( \Gamma \).

Assumption rule:

\[
\frac{}{\alpha \vdash x : \alpha} \quad (\text{Var})
\]

Introduction and elimination rules:

\[
\frac{}{\Gamma \vdash M : \sigma \quad i \text{ fresh}}{\Gamma \vdash !M[i/\sigma]} \quad (\text{Intro})
\]

\[
\frac{}{\Gamma \vdash !M : \tilde{\sigma} \quad \Gamma \vdash !M : \tilde{\tau} \quad \!(\Gamma_1) \quad \!(\Gamma_2)}{\Gamma \vdash !M : \tilde{\tau} \land \tilde{\sigma}} \quad (\land\text{-Intro})
\]

\[
\frac{}{\Gamma \vdash M : \tilde{\sigma} \land \tilde{\tau}} \quad (\land\text{-E-left})
\]

\[
\frac{}{\Gamma \vdash M : \sigma \quad \Gamma \vdash N : \sigma}{\Gamma \vdash \{\Gamma_1, \Gamma_2\} : \sigma} \quad (\text{MP})
\]

\[
\frac{}{\Gamma \vdash \lambda x.M : \sigma}{\Gamma, x : \sigma \vdash M : \tau} \quad (\lambda)
\]

\[
\frac{}{\Gamma \vdash \lambda x.M : \sigma}{\Gamma \vdash \lambda x.M : \sigma \rightarrow \tau} \quad (\lambda!)
\]

\[
\frac{}{\Gamma \vdash M : \sigma \quad \Gamma \vdash U(\sigma)}{\Gamma \vdash U(\Gamma) \vdash M : \sigma} \quad (\text{Inst})
\]

Structural-rules:

\[
\frac{}{\Gamma \vdash M : \sigma}{\Gamma, x : \tau \vdash M : \sigma} \quad \text{if } x \notin \text{dom}(\Gamma) \quad (\text{weak})
\]

\[
\frac{}{\Gamma \vdash M \rightarrow \omega}{\Gamma \vdash \sigma \rightarrow \omega} \quad (\omega)
\]

where

- \( \!(\Gamma) \) means that all variables in \( \Gamma \) are banged (\( \Gamma \) is possibly empty);
- by a slight abuse of notation

\[
\hat{\tau}_u(\Gamma, x : \tau) = \hat{\tau}_u(\Gamma), \!x : \hat{\tau}_u(\tau) \quad \text{and} \quad \hat{\tau}_u(\lambda x.M) = \hat{\sigma}(\tau) \quad \text{if } x \notin \text{Type}^1
\]

\[
\hat{\tau}_u(\Gamma, !x : \tau) = \hat{\tau}_{[\epsilon/i]}(\Gamma, \!x : \tau[\epsilon/i]);
\]

\[
\hat{\tau}_u(\Gamma, \{\Gamma_1, \Gamma_2\}) = \hat{\tau}_{[\epsilon/i]}(\Gamma_1, !x : \tau[\epsilon/i]);
\]

- for \( \Gamma_1, \Gamma_2 \) such that \( \text{dom}(\Gamma_1) \) and \( \text{dom}(\Gamma_2) \) is \( ! \)-prefixed both in \( \Gamma_1 \) and \( \Gamma_2 \);

- \( !x : \sigma \in \Gamma_1 \) or \( x : \sigma \in \Gamma_2, \) then \( x : \sigma \in \Gamma_1 \land \Gamma_2 \);

- \( !x : \sigma \in \Gamma_1 \) and \( x \notin \text{dom}(\Gamma_2) \), or \( !x : \sigma \in \Gamma_2 \) and \( x \notin \text{dom}(\Gamma_1) \), then \( !x : \sigma \in \Gamma_1 \land \Gamma_2 \);

- \( U \) is a substitution, mapping type/index variables to types/indexes, respectively.

We will denote by \( \text{Type}^1 \) and \( \vdash \) the set of types without \( \omega \) and the type system without the \( \omega \)-rule, respectively.

The type system \( \vdash \text{EAL} \) is obtained by giving up the rule \( (\text{!}-\text{Elim}) \) and restricting the rules of \( \vdash \) to \( \lambda \)-terms in \( \Lambda^\text{EAL} \).

Some comments and remarks on the above definitions are in order:
The type connective \( \wedge \) is neither commutative nor idempotent nor associative.

The notion of type equivalence \( \sim \) defined above for the system of Definition 6 is a sharp restriction of the usual type equivalence on intersection types, cf. [8]. The traditional rule does not hold in the involution model of Section 3.

Not all terms of \( \Lambda^1 \) can be typed in \( \vdash \), i.e. without the \( \omega \)-rule, e.g.

\[
\vdash (\lambda x.x)x = \omega, \quad \vdash \lambda x.y.(\lambda z.z)(xy) : (\alpha \rightarrow \omega) \rightarrow (\alpha \rightarrow \omega).
\]

The former is not normalizing, while in the latter pattern matching fails and hence it does not have a strong normal form. Notice however that the type which can be assigned to it records the fact that the two variables can be applied. The meaningfulness of such types is the reason for weakening the traditional definition of type equivalence \( \sim \) as in the system of Definition 6. The issue is rather intricate and will be taken up in Section 4.2.2.

Rule (Inst) could be made redundant by allowing arbitrary types in rule (Var) and arbitrary indices in rule (Intro).

One could consider also second or higher order (possibly recursive) type systems. Their typing strength is subsumed by the \( \wedge \)-rules.

A relevant class of types is that of binary types, which, as we will see in Section 3.1, arise naturally from specifications of partial involutions:

**Definition 7.**

- A type \( \tau \in T \) is binary if each type variable appears at most twice in \( \tau \).
- A judgement \( \Gamma \vdash M : \tau \) is binary if each type variable occurs at most twice in it.

A slight modification of Theorem 30 [11] allows to prove that:

**Proposition 8.** If \( \Gamma \vdash M : \tau \) is derivable, then there exist a binary judgement \( \Gamma' \vdash M : \tau' \) and a substitution \( U \) such that \( U(\Gamma') = \Gamma \) and \( U(\tau') = \tau \).

### 2.1 Abstraction Algorithm

The abstraction algorithm for mapping terms of the \( \lambda^1 \)-calculus into the linear combinatory algebra \( CL^1 \) is a refinement of the standard abstraction algorithm, but this needs to be carefully spelled out so as to factor out as an abstraction algorithm also from \( \lambda^{EAL} \) to \( CL^{EAL} \).

**Definition 9 (Abstraction Algorithms \( A^{\lambda^1} , A^{EAL} \)).**

- Let \( A^{\lambda^1}_{CL} \) denote the set of terms of the \( \lambda^1 \)-calculus obtained by taking combinators as the constants of the calculus. We define \( A^{\lambda^1} : A^{\lambda^1}_{CL} \rightarrow CL^1 \) as in Figure 1, where \( \# \) denotes the modality ! or no modality.
- Let \( A^{EAL}_{CL} \) be the set of \( \lambda^{EAL} \)-terms obtained by taking \( CL^{EAL} \)-combinators as constants. We define \( A^{EAL} : A^{EAL}_{CL} \rightarrow CL^{EAL} \) as the restriction of \( A^{\lambda^1} \) to terms in \( A^{EAL}_{CL} \).
- Vice versa, we denote by \( ( \_ )_{\lambda} : CL^1 \rightarrow A^{\lambda^1} \) the natural mapping of a \( CL^1 \)-term into a \( \lambda \)-term obtained by replacing, in place of each combinator, the corresponding \( A^{\lambda^1} \)-term as follows:

\[
(B)_{\lambda} = \lambda xyz. xy \quad (C)_{\lambda} = \lambda xyz.(xz)y \quad (I)_{\lambda} = \lambda x.x \quad (K)_{\lambda} = \lambda xy.x
\]
\[
(W)_{\lambda} = \lambda xy. xly \quad (D)_{\lambda} = \lambda x.x \quad (\delta)_{\lambda} = \lambda x.x!x \quad (F)_{\lambda} = \lambda xly.l(xy).
\]

The following theorem justifies the above definition. For ease of readability we will often use the notation \( \lambda^1 \# x_1 \ldots \# x_n.M \), for \( M \in CL^1 \), to denote \( A^{\lambda^1}(\lambda^1 \# x_1 \ldots \# x_n.M) \), where \# stands for either the modality ! or no modality (see [18] for more details).
\[ A'(M) \]

\[
\begin{align*}

\end{align*}
\]

Figure 1 The Abstraction Algorithm \( A' : \Lambda_{\text{CL}} \rightarrow \Lambda' \).

\[ \text{Theorem 10 (Soundness of the Abstraction Algorithms } A' \text{ and } A^{EAL} \text{)}.
\]

- Let \( M \in \text{CL}^{EAL}, \) let \( \#M_1, \ldots, \#M_n \in A', \ n \geq 0, \) then
  \( (\lambda x_1 \ldots x_n, M) A'(\#M_1) \ldots A'(\#M_n) \rightarrow^* M[A'(M_1)/x_1, \ldots, A'(M_n)/x_n] \).

- Let \( M \in \text{CL}^{EAL}, \) let \( \#M_1, \ldots, \#M_n \in \Lambda^{EAL}, \ n \geq 0, \) then \( A^{EAL}(M) \in \Lambda^{EAL} \) and moreover:
  \( (\lambda x_1 \ldots x_n, M) A^{EAL}(\#M_1) \ldots A^{EAL}(\#M_n) \rightarrow^* M[A^{EAL}(M_1)/x_1, \ldots, A^{EAL}(M_n)/x_n] \).

The abstraction algorithm in Fig. 1 is implemented in \( \text{A-sym} \), see Section 4.

3 Game Semantics for Combinatory Logics and \( \lambda \)-calculi

In this section, we present the game theoretic semantics of the linear combinatory logic \( \text{CL}^{I} \), and hence of its sublogic \( \text{CL}^{EAL}, \) in terms of partial involutions. Then, via the abstraction algorithm, we obtain a game semantics for terms in \( A^{I} \) and \( \Lambda^{EAL} \). Finally, we present two algorithms, \( \mathcal{T}2\mathcal{T} \) and \( \mathcal{T}2\mathcal{I} \), which relate schematic representations of partial involutions and types.

We start by introducing the model of partial involutions, \( \mathcal{I} \), originally defined by Abramsky in [3] in order to study reversible computations, and studied in [12, 11, 18]. The notion of application on this model amounts to the categorical trace on a subcategory of the category of relations, introduced in [23] (see also [2]).

\[ \text{Definition 11 (The Model of Partial Involutions, } \mathcal{I} \).
\]

- \( T_{\Sigma} \), the language of moves, is defined by the signature \( \Sigma_0 = \{ e \}, \ \Sigma_1 = \{ l, r \}, \Sigma_2 = \{ ( , ) \} \) (where \( \Sigma_i \) is the set of constructors of arity \( i \)); terms \( r(t) \) are output words, while terms \( l(t) \) are input words (often denoted simply by \( rt \) and \( lt \)).
\( \mathcal{I} \) is the set of partial involutions over \( T_\Sigma \), i.e. the set of all partial functions \( f : T_\Sigma \rightarrow T_\Sigma \) such that \( f(t) = t' \Leftrightarrow f(t') = t \);

the operation of replication is defined by \( !f = \{(t, t_1), (t, t_2) \} \mid t \in T_\Sigma \land (t_1, t_2) \in f \} \);

the notion of linear application is defined by \( f \cdot g = I_{!r} \cup (f_{ij} : g : (f_{ij}^* \cdot I_{!r}) \), where \( f_{ij} = \{(t_1, t_2) \mid (i(t_1), j(t_2)) \in f \} \), for \( i, j \in \{r,l\} \) (see diagram below), where "\(^*\)" denotes postfix composition of relations.

\[
\begin{array}{cccc}
\text{in} & \overset{f_{rr}}{\longrightarrow} & \overset{f_{ii}}{\longrightarrow} & \text{out} \\
\cdot & g & \cdot & \cdot
\end{array}
\]

\( \textbf{Proposition 12} \) ([3]). \( \mathcal{I} \) is closed under \(!\)-replication and linear application.

Next we give the notion of schematic specification of the graph of a partial involution, which was introduced in [18] and recall some of its main properties. Schematic specifications induce a substructure of \( \mathcal{I} \) which is still closed under application and replication, and it is sufficient to interpret all combinators, see [18] for full details.

\( \textbf{Definition 13} \) (Schematic Specification). Let \( T_\Sigma[\text{Var}] \) denote the set of terms generated by the signature \( \Sigma \setminus \{e\} \) starting from a set of variables \( \text{Var} \), where we distinguish between term variables \( x, y, \ldots \) and index variables \( i, j, \ldots \), i.e.:

\[ T_\Sigma[\text{Var}] \ni t := x | y \ldots | lt | rt | \langle u, t \rangle \quad \text{where} \quad u := e | i | j \ldots | lu | ru | \langle u,v \rangle . \]

A specification \( P \) of a partial involution is a (possibly infinite) irreflexive set of pairs \( \{t_1 \leftrightarrow t'_1, t_2 \leftrightarrow t'_2, \ldots\} \), where:

(i) \( t_1, t'_1 \in T_\Sigma[\text{Var}] \);

(ii) a single pair \( t_1 \leftrightarrow t'_1 \) represents both \( (t_1, t'_1) \) and \( (t'_1, t_1) \);

(iii) in any pair \( t_i \leftrightarrow t'_i \) exactly one term variable appears, once in \( t_i \) and once in \( t'_i \);

(iv) for any pairs \( t_i \leftrightarrow t'_i, t_j \leftrightarrow t'_j \), \( t_i \) is not an instance of \( t_j \).

Schematic specifications generate graphs of partial involutions as follows:

\( \textbf{Definition 14} \) (\( \mathcal{G} \)). Given a schematic specification \( P \), the set \( \mathcal{G}(P) \) is the symmetric closure of the set \( \{(U(t_1), U(t_2)) \mid (t_1 \leftrightarrow t_2) \in P \land U : T_\Sigma[\text{Var}] \rightarrow T_\Sigma \} \).

The following lemma follows immediately from the above definitions:

\( \textbf{Lemma 15}. \) If \( P \) is a specification, then \( \mathcal{G}(P) \) is the graph of a partial involution on \( T_\Sigma \).

Not all partial involutions are generated by specifications, e.g. the relation \( \{re \leftrightarrow le\} \) is trivially not induced by any specification.

A notion of composition on specifications, which corresponds to composition on partial involutions can be defined as follows:

\( \textbf{Definition 16} \) (Composition of Specifications). Let \( P, P' \) be specifications. We define

\[
P; P' = \{(t, t') \mid \exists (t_1, t_2) \in P, (t'_1, t'_2) \in P', U. (U = U(t_1, t'_1) \land t = U(t_2) \land t' = U(t'_2))\} ,
\]

where \( U(t_2, t'_1) \) is the most general unifier of \( t_2 \) and \( t'_1 \).

This definition essentially amounts to composition in Clause Algebras, as in [19].

The above definitions permits to define a notion of application between specifications, \( P \cdot P' \), which mimics the one between partial involutions in Definition 11.
Lemma 17 ([18]). Let \( P, P' \) be specifications. Then

(i) \( \mathcal{G}(P; P') = \mathcal{G}(P); \mathcal{G}(P') \);

(ii) \( \mathcal{G}(P \cdot P') = \mathcal{G}(P) \cdot \mathcal{G}(P') \).

One can easily check that:

Lemma 18 ([18]). The substructure of \( I \) induced by schematic specifications is closed under application and replication.

Now we are in the position of giving the interpretation in \( I \) of CL', by defining the schematic specifications of the graphs of the combinators.

Definition 19 (Game Semantics of CL'). The combinatory logic CL' is interpreted in \( I \) as in Figure 2, where we use the abbreviation \( l^n t \) for the terms \( l \ldots l t \), and \( r^n t \) for the terms \( r \ldots r t \).

In following proposition for (i) see [3], for (ii) see [11].

Proposition 20.

(i) \( I \) is a model of CL', and hence of the combinatory sublogic CL'^EAL.

(ii) \( I \) is a model of all the reduction rules of \( \Lambda^1 \), but the \( \xi \)-rules.

Using the semantics for CL'-combinators defined in Figure 2, and the abstraction algorithm described in Section 2.1, one can derive the partial involution corresponding to a given \( \lambda \)-term, by repeatedly applying our implementation of linear application on involutions (see Appendix A). However, not all interpretations of CL'-combinators are partial involutions with finite specifications, since graphs of finite specifications are not closed under linear application. E.g. the fixed point combinator \((\lambda^*x'y.y((x'y)y'x)x'((x'y)y'x))\) has an infinite specification. This is taken care of in \( \Lambda \)-symsym by outputting the stream of pairs in the partial specification.

3.1 Correspondence Algorithms, \( \mathcal{T}2\mathcal{T}, \mathcal{T2I} \)

Here we present the two algorithms, \( \mathcal{T}2\mathcal{T} \) and \( \mathcal{T2I} \), which relate schematic representations of partial involutions and types in Type'. The first algorithm, given a schematic specification of a partial involution, yields a binary type, the latter, given a binary type, provides a schematic specification of a partial involution. The two transformations are one inverse of the another over suitable domains of schematic specifications and types.
We begin by explaining how the algorithm \( T2T \) works. First of all, we need the following \( \text{build}_\text{type}_\text{tree}( ) \) function, in order to build a skeleton type tree from a term \( t \in T_{2}[\text{Var}] \). The function definition is syntax driven:

\[
\text{build}_\text{type}_\text{tree}(t) = \begin{cases} 
\alpha_x & \text{if } t \equiv x \\
\text{build}_\text{type}_\text{tree}(t') \rightarrow _\_ & \text{if } t \equiv lt' \\
_\_ \rightarrow \text{build}_\text{type}_\text{tree}(t') & \text{if } t \equiv t' \\
_\_ \rightarrow \text{build}_\text{type}_\text{tree}(t') & \text{if } \tau \equiv \langle u, t' \rangle \\
\text{build}_\text{type}_\text{tree}(\langle u', t' \rangle \wedge _\_) & \text{if } t \equiv \langle u, t' \rangle \text{ and } l \text{ is the leftmost } l/r \text{ constructor in } u \text{ and } u' \text{ is obtained from } u \text{ by erasing it} \\
\text{build}_\text{type}_\text{tree}(\langle u', t' \rangle) & \text{if } t \equiv \langle u, t' \rangle \text{ and } r \text{ is the leftmost } l/r \text{ constructor in } u \text{ and } u' \text{ is obtained from } u \text{ by erasing it}
\end{cases}
\]

where the underscore characters (\_) above stand for “missing parts” of the resulting type tree. Such holes will be (hopefully) filled in by successive unifications, as explained below.

Hence, for each rule \( t_i \leftrightarrow t'_i \) (for \( i = 1, \ldots, n \)) of a given specification, we compute the two (partial) types \( \text{build}_\text{type}_\text{tree}(t_i) \) and \( \text{build}_\text{type}_\text{tree}(t'_i) \). Finally, we try to unify all such partial types, over all rules. If we succeed, we infer a type representing the original partial specification; otherwise, we fail. Notice that the possible final type may still contain “holes”. E.g. partial specifications of erasing terms do not exhibit any rule for the variable which is erased.

Due to the peculiar syntax of types in \( \text{Type}_1 \), unification of types is not a plain unification \( \text{à la} \) Robinson. Indeed, we have subcases which may need to spawn \( \wedge \)-constructors in order to instantiate new instances of some types. For instance, a !-subtype like \( !_u \sigma \) may need to spawn new instances of \( !_u \sigma' \wedge !_u \sigma'' \wedge \ldots \), in order to unify against another type. In our implementation, we implement such spawnings in order to ease the unification process as much as possible. At the end there can be some leftovers of those spawning activities; thus, we implement a sort of “garbage collector” which takes care of those dummy \( \wedge \)’s, before returning the final type-candidate to the user.

Another subtle issue comes from the fact that the order in which the pairs of the specification are processed may imply success or failure in the unification process (because the spawning of \( \wedge \)-constructors must trigger at the right moment). Hence, we restart the procedure until a type is found, permuting in all possible ways the pairs in the specification.

Finally, the type synthesis algorithm may fail, totally or partially. Total failure can be easily detected, since the algorithm returns \( \Omega \), meaning that it was not able to build even a partial skeleton. On the other hand, partial failure occurs when the algorithm does not succeed in recovering a complete type tree from the partial specification, i.e., there remain some “holes” to be filled in. Such holes are marked by placeholders of the form \( \Omega_i \), where \( i \) is some integer index. Such \( \Omega_i \)’s correspond to the underscore characters generated by the \( \text{build}_\text{type}_\text{tree}( ) \) function above which have not been instantiated by the type unification algorithm. We could safely replace them with a plain \( \Omega \), since the type \( \omega \) is a wild card, but we do not make this choice in the web tool, see Section 4.2.2.

The other way round is dealt with by the algorithm \( T2I \). Here the input can be any type and the output is a specification of a symmetric relation; if the input type is binary, then the result is the specification of a partial involution. The algorithm processes all type variables occurring in a given type by means of the function \( \text{var}_\text{-type}2PI \), which produces a list \( L \) of partial specification terms. If the type is binary the list has at most length 2. The
partial specification rules for that type variable are obtained by combining in all possible ways the terms of \( L \). Repeating this procedure for all type variables of a type, we recover the corresponding partial specification. We give only \( \text{var\_type2PI} \):

\[
\begin{array}{l}
\text{var\_type2PI}(\alpha, \tau) \\
\begin{cases}
[x_\alpha] & \text{if } \tau \equiv \alpha \\
\text{l}(\text{var\_type2PI}(\alpha, \tau')) + + & \text{if } \tau \equiv \tau' \rightarrow \tau'' \\
\text{r}(\text{var\_type2PI}(\alpha, \tau'')) & \text{if } \tau \equiv \tau' \rightarrow \tau'' \\
\text{l}(\text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv \tau' \rightarrow \tau'' \\
\text{r}(\text{var\_type2PI}(\alpha, \tau'')) & \text{if } \tau \equiv \tau' \rightarrow \tau'' \\
\text{add\_index}(u, \text{var\_type2PI}(\alpha, \bigwedge^m_{i=1} \neg v_i \tau_i)) & \text{if } \tau \equiv \bigwedge^m_{i=1} \neg v_i \tau_i \\
\text{compose\_index}(l, \text{var\_type2PI}(\alpha, \tau')) + + & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{compose\_index}(r, \text{var\_type2PI}(\alpha, \tau'')) & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{compose\_index}(l, \text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{compose\_index}(r, \text{var\_type2PI}(\alpha, \tau'')) & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{add\_index}(u, \text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv !_u \tau' \land \tau'' \\
\text{add\_index}(u, \text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv !_u \tau' \land \tau'' \\
\text{compose\_index}(c, L) & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{add\_index}(u, \text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv !_u \tau' \land \tau'' \\
\text{compose\_index}(c, L) & \text{if } \tau \equiv \tau' \land \tau'' \\
\text{add\_index}(u, \text{var\_type2PI}(\alpha, \tau')) & \text{if } \tau \equiv !_u \tau' \land \tau'' \\
\end{cases}
\end{array}
\]

where:
- \( \text{fv}(\tau) \) is the set of free variables of type \( \tau \);
- in the expression \( \tau \equiv \bigwedge^m_{i=1} \neg v_i \tau_i \) the right-hand side term denotes the atomic components of \( \tau \);
- \( ++ \) is the list concatenation operator;
- the functions \( \text{l}() \) and \( \text{r}() \), when applied to a list (i.e., the return type of \( \text{var\_type2PI}() \)), distribute, respectively the \( \text{l} \) and \( \text{r} \) constructors at the head of all elements of the list, i.e., each \( t \in L \) will be substituted by \( lt \) (resp. \( rt \));
- \( \text{compose\_index}(c, L) \) (where \( c \) is either \( l \) or \( r \)) is a function distributing the constructor \( c \) to all the pairs of the list \( L \), i.e., each \( \langle u, t \rangle \in L \) will be substituted by \( \langle cu, lt \rangle \);
- \( \text{add\_index}(u, \text{list} \) is a function distributing the index \( u \) to all elements of the list \( L \), i.e., each \( \text{list} \) will be substituted by \( \langle u, list \rangle \).

Notice that in dealing with types whose outermost constructor is \( \land \), we distinguish between the cases where all atomic components have a common prefix in their \( 's, denoting that promotions have been carried after the \( \land \) operations, and the cases where there is no such common prefix, where the \( \land \)-constructor was indeed the last to be used in producing the type.

It is easy to check that:

► **Lemma 21.**
1. For any specification \( P \) of a partial involution, \( T2T(P) \) is a binary type.
2. For any binary type \( \tau \), \( T2T(\tau) \) is a specification of a partial involution.
The two transformations, $T_2T$ and $T_2I$, are the inverse of one another in the sense:

**Conjecture 22.**
1. Let $M \in \Lambda$ be a closed term which reduces to a term in strong normal form, without the use of the $\xi$-rules, then: $\vdash M : T_2T([M]^2)$ and $T_2I(T_2T([M]^2)) = [M]^2$.
2. Let $\tau$ be a binary type, then $T_2T(T_2I(\tau)) = \tau$.

When a closed term $M \in \Lambda$ needs the $\xi$-rules to reduce to strong normal form its semantics as a partial involution does not necessarily yield an immediately meaningful type. We will discuss this issue further in Section 5.

Conjecture 22 applies also when we restrict to terms of $\Lambda^{EAL}$.

## 4 The Web Tool $\Lambda$-symsym

In the following, we will illustrate how to use the web tool, $\Lambda$-symsym, available at [http://158.110.146.197:31780/automata/](http://158.110.146.197:31780/automata/), in order to experiment with the algorithms provided in the previous section. We will provide excerpts from various sessions illustrating how to convert $\lambda$-terms to combinators, from the latter to partial involutions, and finally to types. Moreover, we will also show how to infer a partial involution from a type. The web tool is implemented in the language Erlang, [17]. We chose this language because of its rich pattern matching features, its flexible constructors such as the set data type and for the large number of libraries which allow for a rapid prototyping. The fine details of the implementation appear in [13].

### 4.1 Encoding $\lambda$-terms, partial involutions and types

First we give the syntax representation; the following tables contain the correspondences between the syntax we use with “pencil and paper”, the actual input syntax and the internal representation used by our algorithms.

<table>
<thead>
<tr>
<th>$\lambda$-terms</th>
<th>On the paper</th>
<th>Input syntax</th>
<th>Internal representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x$</td>
<td>$X$</td>
<td>{var, &quot;X&quot;}</td>
<td></td>
</tr>
<tr>
<td>$C$</td>
<td>$C$</td>
<td>{comb, $C$}</td>
<td></td>
</tr>
<tr>
<td>$MN$</td>
<td>$M@N$</td>
<td>{lapp, $M$, $N$}</td>
<td></td>
</tr>
<tr>
<td>$\lambda x.M$</td>
<td>$l*X.M$</td>
<td>{abs, {var, &quot;X&quot;}, $M$}</td>
<td></td>
</tr>
<tr>
<td>$\lambda !x.M$</td>
<td>$l*!X.M$</td>
<td>{abs_b, {var, &quot;X&quot;}, $M$}</td>
<td></td>
</tr>
<tr>
<td>$!M$</td>
<td>$!M$</td>
<td>{bang, $M$}</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Partial Involutions</th>
<th>On the paper</th>
<th>Input syntax</th>
<th>Internal representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$e$</td>
<td>$e$</td>
<td>$e$</td>
<td></td>
</tr>
<tr>
<td>$x$</td>
<td>$X$</td>
<td>{var, &quot;X&quot;}</td>
<td></td>
</tr>
<tr>
<td>$lM$</td>
<td>$lM$</td>
<td>{l, $M$}</td>
<td></td>
</tr>
<tr>
<td>$rM$</td>
<td>$rM$</td>
<td>{r, $M$}</td>
<td></td>
</tr>
<tr>
<td>$\langle M, N \rangle$</td>
<td>$&lt;M,N&gt;$</td>
<td>{p, {M, N}}</td>
<td></td>
</tr>
<tr>
<td>$M \leftrightarrow N$</td>
<td>$M &lt;&gt; N$</td>
<td>{{M, N}, {N, M}}</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Types</th>
<th>On the paper</th>
<th>Input syntax</th>
<th>Internal representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\alpha$</td>
<td>$A$</td>
<td>{var, &quot;A&quot;}</td>
<td></td>
</tr>
<tr>
<td>$\alpha \to \beta$</td>
<td>$A \rightarrow B$</td>
<td>{map, $A$, $B$}</td>
<td></td>
</tr>
<tr>
<td>$\alpha \land \beta$</td>
<td>$A \land B$</td>
<td>{cap, $A$, $B$}</td>
<td></td>
</tr>
<tr>
<td>$!\alpha$</td>
<td>$!I M$</td>
<td>{bang, $I$, $M$}</td>
<td></td>
</tr>
</tbody>
</table>

The web tool is implemented in the language Erlang, [17]. We chose this language because of its rich pattern matching features, its flexible constructors such as the set data type and for the large number of libraries which allow for a rapid prototyping. The fine details of the implementation appear in [13].
4.1.1 The web interface

Figure 3 depicts the web interface we can use to call the algorithms. It has 4 components:
1. a green drop-down menu allowing the user to choose the function to execute (e.g., `lambda2type()` in the general setting, as it appears in Figure 3); it provides a number of functions for the general case, $\Lambda$ and for the $\Lambda^{EAL}$ case, namely:
   (i) the function `lambda2type()` which given a term produces its combinatory logic translation, its semantics as a specification of a partial involution, and the type corresponding to the specification;
   (ii) the function `show_partial_involution` which produces a specification of a partial involution, given a type;
   (iii) the function `show_type` which yields a type given a partial involution;
   (iv) more functions which have not been discussed in this paper for dealing with polynomial terms, and Hindley-Milner Types;
2. a text area where the user can write the argument to pass to the selected function;
3. another text area where the result will appear after clicking the button “Compute”;
4. a red button (“Compute”) to start the computation.

4.2 Sessions

4.2.1 Strictly Linear Combinators in $I$ are a $\lambda$-algebra

One can see that the partial involutions corresponding to the two terms in input are equal. This is one of the many equations which need to be checked to show that the $\xi$ rule holds.

Input:
1*Y1*Y1*Z.X0(Y2Z)
Combinators abstraction:
((CC((BB)((BB)I)))((CC((BB)I)))1)
Partial involution rules:
--- begin ---
1(r(_X7)) <-> r(r(r(_X7)))
1(l(_X7)) <-> r(1(r(_X7)))
--- end ---
Principal type:
((_X10 -> _X9) -> ((_X8 -> _X10) -> (_X8 -> _X9)))

Input:
B
Partial involution rules:
--- begin ---
r(r(r(_X1))) <-> l(r(_X1))
l(l(_X1)) <-> r(l(r(_X1)))
--- end ---
Principal type:
((_X4 -> _X3) -> ((_X2 -> _X4) -> (_X2 -> _X3)))

4.2.2 The $\xi$-rule fails for erasers

The following example shows that the $\xi$-rule fails in $I$ when terms erase variables. The session on the right hand side shows that erased subterms might still leave an echo in the partial involution. This is the reason why we have not taken the standard $\omega$-equivalence
as for intersection types. Please bear in mind that, when an inferred type features some \(_\Omega_i\) variables (for \(i=1,2,3\ldots\)), these variables stand for placeholders for any type. They are “holes” in the type tree structure which arise since partial involutions do not provide unnecessary information.

\[
\text{Input:} \quad \lambda X. Y. \lambda Y. (\lambda Z. \lambda X (X Y)) \\
\text{Combinators abstraction:} \quad (B (B (K I)) (C (B (B Z)))) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
r (r (r (X _4))) \leftrightarrow r (r (r (X _4))) \\
l (l (X _4)) \leftrightarrow r (l (X _4)) \\
--- \text{end} --- \\
\text{Principal type:} \quad (\_X _5 \rightarrow \_\Omega _3) \rightarrow (\_X _5 \rightarrow (\_X _6 \rightarrow \_X _6))
\]

\[
\text{Input:} \quad \lambda X. \lambda Y. \lambda Z. Z \\
\text{Combinators abstraction:} \quad (K I) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
r (r (l (X _2))) \leftrightarrow r (r (X _2)) \\
--- \text{end} --- \\
\text{Principal type:} \quad (\_\Omega _1 \rightarrow (\_\Omega _2 \rightarrow (\_X _3 \rightarrow \_X _3)))
\]

4.2.3 The \(\xi\)-rule fails when modalities are erased

As was the case in the above example, also in this case there remains an echo in the partial involution when modalities are erased.

\[
\text{Input:} \quad \lambda X. D \rightarrow ! X \\
\text{Combinators abstraction:} \quad ((B D) (F! (I))) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
l (l (l (e), l (e))) \leftrightarrow r (r (r (X _1))) \\
l (l (l (e), l (e))) \leftrightarrow l (r (l (l (e), r (X _1)))) \\
--- \text{end} --- \\
\text{Principal type:} \quad ((! e (\_X _2) \rightarrow \_X _2))
\]

4.2.4 The \(\xi\)-rule fails in general

The following sessions illustrate that the \(\xi\)-rule fails in the encoding of standard \(\lambda\)-calculus via application in the Kleisli category. This issue will be briefly discussed in Section 5.

\[
\text{Input:} \quad \lambda X. (\lambda Y. Y \rightarrow ! X) @ X \\
\text{Combinators abstraction:} \quad (B ((C (B (B D))) (F! (I)))) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
l (r (r (X _1))) \leftrightarrow r (r (r (X _1))) \\
l (l (X _4)) \leftrightarrow r (l (X _4)) \\
--- \text{end} --- \\
\text{Principal type:} \quad ((\_\Omega _6 \rightarrow (\_\Omega _4 \rightarrow \_X _2)) \rightarrow \_X _2)
\]

\[
\text{Input:} \quad \lambda X. D \rightarrow ! X \\
\text{Combinators abstraction:} \quad (W ((C (B (B (B D))) (F! (I)))) (B (B ((C (B (B D))) (F! (I))))) d) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
l (r (l (l (e), r (r (X _1)))) \leftrightarrow l (r (r (X _1))) \\
l (l (r (r (X _1)))) \leftrightarrow l (r (r (X _1))) \\
--- \text{end} --- \\
\text{Principal type:} \quad ((((! e (\_X _2) \rightarrow \_X _2))) \rightarrow \_X _2)
\]

\[
\text{Input:} \quad \lambda X. (\lambda Y. Y \rightarrow ! X) @ X \\
\text{Combinators abstraction:} \quad ((B ((C (B (B (B D))) (F! (I)))) (B (B ((C (B (B D))) (F! (I))))) d) \\
\text{Partial involution rules:} \quad --- \text{begin} --- \\
r (r (X _1)) \leftrightarrow l (l (l (e), r (X _1))) \\
l (l (r (X _1))) \leftrightarrow l (l (l (e), r (X _1))) \\
--- \text{end} --- \\
\text{Principal type:} \quad (((! e (\_X _2) \rightarrow \_X _2))) \rightarrow \_X _2
\]
4.2.5 Church Binary Words in the $\lambda^{EAL}$-calculus

This is the encoding of Church binary word $<0,0,1>$ as would appear in [6].

Input:
$$l^*!\mathbf{X}.l^*!\mathbf{Y}.!(l^*\mathbf{Z}.\mathbf{X}@(\mathbf{X}@\mathbf{Y}@\mathbf{Z}))$$

Combinators abstraction:

A Erlang implementation of application between specifications of partial involutions

The definition of linear application between specifications of partial involutions follows the definition in [3], namely the flow diagram in Definition 11 (see Section 3). Given $f$, $g$, $f \cdot g = f_{rr} \cup f_{rl}; g; f_{lr}; (f_{ll}; g^*)$ where $f_{ij} = \{(u, v) \mid (i(u), j(v)) \in f\}$ for $i, j \in \{l, r\}$. Hence, we must begin by implementing a function `extract`, which infers $l$- and $r$- rewriting rules from the partial involution represented by the list $L$, according to $Op1$ and $Op2$:

```erlang
extract(L,Op1,Op2) ->
  case L of
    [] -> [];
    [{e,_}|T] -> extract(T,Op1,Op2);
    [(_,e)|T] -> extract(T,Op1,Op2);
    [{p,_,_}|T] -> extract(T,Op1,Op2);
    [(_,p,_,_)|T] -> extract(T,Op1,Op2);
    [{T1,T2}|T] ->
      if (Op1==Op1) and (Op2==Op2) ->
        [{S1,S2} | extract(T,Op1,Op2)];
      true ->
        extract(T,Op1,Op2)
    end.
  end.
```

Thus, if $F$ represents a partial involution, then `extract(F,r,L)` will compute $F_{rl}$.

Then, we define the core function `composeRuleList` which composes rule $R1 \rightarrow R2$ with all the rules in $L$ (exploiting the natural unification and substitution functions):

```erlang
composeRuleList(R1,R2,L) ->
  case L of
    [] -> [];
    [{S1,S2}|T] ->
      if 
        (ExitStatus==ok) ->
          [{subListTerm(MGU,R1),subListTerm(MGU,S2)} | composeRuleList(R1,R2,T)];
        true -> composeRuleList(R1,R2,T)
      end.
  end.
```
In order to avoid possible clashes between variable names, the `alpha` function defined below replaces all variables in Ruleset1 which also occur in Ruleset2 with freshly generated ones:

```erlang
alpha(Ruleset1, Ruleset2) ->
    Vars1 = ruleListVars(Ruleset1),
    Vars2 = ruleListVars(Ruleset2),
    FreshSubst = separateVars(Vars1, Vars2),
    subListRuleset(FreshSubst, Ruleset1).
```

`alpha` is used fruitfully in the definition of `compose` which computes all possible chainings between rewriting rules of L1 and L2:

```erlang
compose(L1, L2) ->
    L1_Fresh = alpha(L1, L2),
    compose_fresh(L1_Fresh, L2).
```

```erlang
compose_fresh(L1_Fresh, L2) ->
    case L1_Fresh of
        [] -> [];
        [H1|T1] -> {R1, R2} = H1,
                   composeRuleList(R1, R2, L2) ++ compose_fresh(T1, L2)
    end.
```

The function `star` capitalizes on the definition of `compose`, in order to implement the computation of \( H; (F;G)^* \):

```erlang
star(H, F, G) ->
    S = compose(H, F),
    if
        S == [] -> H;
        true -> T = compose(S, G),
                if
                    T == [] -> H;
                    true -> H ++ star(T, F, G)
                end
    end.
```

At this point, the implementation of linear application, according to Definition 11 of Section 3, is straightforward:

```erlang
lapp(F, G) ->
    FRR = extract(F, r, r),
    FRL = extract(F, r, l),
    FLL = extract(F, l, l),
    FLR = extract(F, l, r),
    FRL_G = compose(FRL, G),
    FRL_G_STAR = star(FRL_G, FLL, G),
    FRR ++ compose(FRL_G_STAR, FLR).
```
