On the Logical Strength of Confluence and Normalisation for Cyclic Proofs

Anupam Das
University of Birmingham, UK

Abstract

In this work we address the logical strength of confluence and normalisation for non-wellfounded typing derivations, in the tradition of “cyclic proof theory”. We present a circular version $CT$ of Gödel’s system $T$, with the aim of comparing the relative expressivity of the theories $CT$ and $T$. We approach this problem by formalising rewriting-theoretic results such as confluence and normalisation for the underlying “coterm” rewriting system of $CT$ within fragments of second-order arithmetic.

We establish confluence of $CT$ within the theory $RCA_0$, a conservative extension of primitive recursive arithmetic and $IΣ_1$. This allows us to recast type structures of hereditarily recursive operations as “coterm” models of $T$. We show that these also form models of $CT$, by formalising a totality argument for circular typing derivations within suitable fragments of second-order arithmetic. Relying on well-known proof mining results, we thus obtain an interpretation of $CT$ into $T$; in fact, more precisely, we interpret level-$n$-$CT$ into level-$(n+1)$-$T$, an optimum result in terms of abstraction complexity.

A direct consequence of these model-theoretic results is weak normalisation for $CT$. As further results, we also show strong normalisation for $CT$ and continuity of functionals computed by its type 2 coterm.

1 Introduction

Cyclic (or circular) proofs have attracted increasing attention in recent years, in settings including modal fixed point logics [28, 16, 35, 1, 18], predicate logic [8, 9, 7, 6], algebras [31, 14, 15, 13], arithmetic [33, 5, 11] and type systems [19, 4, 3]. In short, cyclic proofs are possibly non-wellfounded derivations ("coderivations") that have only finitely many distinct subderivations (and so are finitely presentable). That they are meaningful (i.e., sound, total, terminating, etc.) is usually guaranteed by some $ω$-regular correctness condition at the level of their infinite branches.
In this work we investigate the interface between theories of arithmetic and type systems. These two settings are fundamentally related by means of well-known proof interpretations, such as the functional and realisability interpretations (see, e.g., [2, 24]). In particular Gödel’s system $T$, a simply typed classical quantifier-free theory with recursion and induction, is capable of interpreting all of Peano Arithmetic, effectively trading off quantifier complexity for abstraction complexity (i.e. type level).

Inspired by the aforementioned previous work on circular type systems, we present a circular version, $CT$, of $T$, and compare the relative expressivity of (fragments of) the two theories. More precisely, we show that the restriction of $CT$ to level $n$ ($CT_n$) is interpreted in the restriction of $T$ to level $n + 1$ ($T_{n+1}$). This result is optimal due to a converse result in parallel work [12] (that is beyond the scope of the present paper).\(^1\)

Since non-wellfounded derivations do not directly admit inductive arguments and their correctness relies on nontrivial infinitary combinatorics, we employ a “proof mining” approach towards establishing this interpretation. More precisely, we formalise models of $CT_n$ within fragments of (second-order) arithmetic, and rely on the aforementioned proof interpretations to extract corresponding terms of $T_{n+1}$. This builds on analogous aforementioned work in the arithmetic setting, namely [33, 11], also taking advantage of second-order theories.

Our formalisation requires us to establish a form of confluence for the underlying rewrite system of $CT$, which we show holds in one of the weakest second-order theories RCA$_0$, essentially a form of primitive recursive arithmetic with quantification over sets. Showing that these structures indeed constitute models of $CT$ requires a formalisation of the totality argument for circular derivations, with quantifiers relativised to this structure.

A direct consequence of these model-theoretic results is weak normalisation for coterms of $CT$. As further results, we also show strong normalisation for $CT$ and continuity of functionals computed by its type 2 coterms.

**Relation to other work.** In [26] the authors present a circular version of the underlying type system of $T$, using a slightly different type language including a Kleene $\ast$. In particular, they show that circular derivations compute, in the standard model, just the primitive recursive functionals at type 1, i.e. the natural number functions computed by terms of $T$, also using a formalisation within second-order theories of arithmetic. We generalise that result in several ways: (a) we optimise the result with respect to abstraction complexity; (b) we give a logical correspondence, at the level of theories, not just the standard model; (c) we give bona fide confluence and normalisation results for the underlying rewrite system on coterms.

This work is based on part of the (unpublished) preprint [12], where related results, proofs and examples may be found.

**Preliminaries.** We shall assume some basic familiarity with the underlying technical disciplines of this work, which are now well-established and form the subjects of multiple monographs. In particular, these include rewriting theory [37], subsystems of second-order arithmetic [34, 22], and Gödel’s system $T$ and program extraction [2, 24]. Some familiarity with higher-order computability [27] and metamathematics [20, 23, 38] is also helpful.

---

\(^1\) It is easy, however, to see that $T_n$ is interpreted in $CT_n$, as we will see in Example 2.5.
Throughout this work we shall work with theories that are simply or finitely typed. Namely types, written \( \sigma, \tau \) etc., are generated by the following grammar:

\[
\sigma, \tau ::= N \mid (\sigma \to \tau)
\]

A simply typed theory is a multi-sorted (classical) first-order theory, whose sorts are just the simple types, equipped with application operators \( \circ_{\sigma,\sigma\to\tau} \) for each pair \( \sigma, \sigma \to \tau \) of types, as usual. (Typed) terms, written \( s, t \) etc., are formed from constants of a simply typed language under typed application. We simply write \( ts \) for the application of a term \( t \) of type \( \sigma \to \tau \) to a term \( s \) of type \( \sigma \). As usual we may sometimes omit parentheses, e.g. writing \( rst \) instead of \( (((rs)t) \).

In this work, we always assume intensional equality for simply typed theories. Namely we have binary relation symbols \( =_\sigma \) for each type \( \sigma \), axiomatised by reflexivity, \( t =_\sigma t \), and the Leibniz property, \( (s =_\sigma t \land \varphi(s)) \supset \varphi(t) \), for each formula \( \varphi \) and terms \( s, t \) of type \( \sigma \).

### 2.1 Sequent calculus presentation of \( T \) terms

Sequent calculi give us a way to write typed terms that are more succinct with respect to type level, and also enjoy elegant proof theoretic properties, e.g. cut-elimination. Importantly, the induced relations between type occurrences makes it easier to define our correctness criterion for non-wellfounded derivations later.

- **Definition 2.1 (Sequent calculus).** Sequents are expressions \( \vec{\sigma} \vdash \tau \), where \( \vec{\sigma} \) is a list of types and \( \tau \) is a type. The typing rules for \( T \) are given in Figure 1.

Here, and throughout this subsection, colours of each type occurrence in typing rules may be ignored for now and will become relevant later in Section 2.2.

Each rule instance (or step) determines a constant of the appropriate type. E.g., a step
\[
\vec{\sigma} \vdash \rho, \vec{\sigma} \vdash \sigma \quad \Rightarrow \quad \vec{\sigma} \vdash \tau
\]
is a constant of type \( (\rho \to \sigma) \to (\vec{\sigma} \to \tau) \to \tau \). In this way, we may identify each derivation with a term obtained by just repeatedly applying rule instances, starting from the conclusion, to its subderivations. Note that this “combinatory” approach, treating rule instances as constants rather than, say, meta-level operations on \( \lambda \)-terms, ensures that this association of a term to a derivation is continuous. This is important for our later association of “coterm” to a “coderivation”.

---

2 Here and elsewhere we freely write, say, \( \vec{\sigma} \vdash \rho \) for \( \rho_1 \to \cdots \to \rho_n \to \rho \) when \( \vec{\rho} \) is a list \( (\rho_1, \ldots, \rho_n) \).

\[
\begin{align*}
\text{id } x &= x \\
\text{ex } t \overline{x} x y \overline{y} &= t \overline{x} y x \overline{y} \\
\text{wk } t \overline{x} x &= t \overline{x} \\
\text{cntr } t \overline{x} x &= t \overline{x} x x \\
\text{cut } s t \overline{x} &= t \overline{x} (s \overline{x}) \\
\text{L } s t \overline{x} y &= t \overline{x} (y (s \overline{x})) \\
\text{R } t \overline{x} x &= t \overline{x} x
\end{align*}
\]

\begin{itemize}
\item \textbf{Figure 2} Equational axiomatisation of \( T \), where \( z \) is a variable of type \( N \).
\end{itemize}

1. \( \neg sx = 0 \)
2. \( sx = sy \supset x = y \) (Ind) If \( \vdash \varphi(0) \) and \( \vdash \varphi(x) \supset \varphi(sx) \) then \( \vdash \varphi(t) \), for \( \varphi \) quantifier-free.

\begin{itemize}
\item \textbf{Figure 3} Number-theoretic axioms for \( T \), where \( x \), \( y \) and \( t \) are variables/a term of type \( N \).
\end{itemize}

A term of the form \( \overline{n} \ldots \overline{0} \) is called a \textbf{numeral}, and is more succinctly written just \( n \).

► \textbf{Definition 2.2 (System \( T \))}. \( T \) is the simple type theory over the language given by Figure 1, axiomatised by the formulas and rules from Figure 2 and Figure 3.

► \textbf{Remark 2.3 (Standard model)}. We may consider usual Henkin structures for simply typed theories, called \textbf{type structures}. One particular structure, the “standard” or “full set-theoretic” model \( \mathfrak{N} \), is given by the following interpretation:

\begin{itemize}
\item \( N^\mathfrak{N} = \mathbb{N} \) and \( (\sigma \rightarrow \tau)^\mathfrak{N} \) is the set of functions \( \sigma^\mathfrak{N} \rightarrow \tau^\mathfrak{N} \).
\item \( 0^\mathfrak{N} := 0 \in \mathbb{N} \) and \( s^\mathfrak{N}(n) := n + 1 \).
\item The other constants of \( T \) are interpreted by (higher-order) functionals by taking the equations from Figure 2 as definitions, left-to-right.
\item Given \( f \in \sigma^\mathfrak{N} \) and \( g \in (\sigma \rightarrow \tau)^\mathfrak{N} \), \( g \circ \mathfrak{N} f \in \tau^\mathfrak{N} \) is defined as \( g(f) \).
\item For each type \( \sigma \), we have an \textbf{extensional} equality relation \( =^\mathfrak{N}_\sigma \):

\begin{itemize}
\item \( =^\mathfrak{N}_N \) is just equality of natural numbers;
\item for \( f, g \in (\sigma \rightarrow \tau)^\mathfrak{N} \), we have \( f =^\mathfrak{N}_{\sigma \rightarrow \tau} g \) just if \( \forall x \in \sigma^\mathfrak{N}. f(x) =^\mathfrak{N}_\tau g(x) \).
\end{itemize}
\end{itemize}

It is clear, by reduction to induction at the meta-level, that the interpretations of the constants above are well-defined, and that the axioms of Figure 3 (as well as Figure 2) are satisfied in \( \mathfrak{N} \). Thus \( \mathfrak{N} \) constitutes a bona fide model of \( T \).

2.2 “Coderivations” and a correctness condition

\textbf{Coterms} are generated \textit{coinductively} from constants and variables under typed application. Formally, we may construe a coterm as a possibly infinite binary tree (of height \( \leq \omega \)) where each leaf (if any) is labelled by a typed variable or constant and each interior node is labelled by a typed application operation, having type consistent with the types of its children. I.e., an interior node with children of types \( \sigma \) and \( \sigma \rightarrow \tau \), respectively, must have type \( \tau \).

Similarly, a \textbf{coderivation}, is a possibly non-wellfounded tree built from the derivation rules of Figure 1. As for (well-founded) derivations and terms, we treat coterivations as coterms in the natural way. We say that a coderivation or coterm is \textbf{regular} (or \textbf{circular}) if it has finitely many distinct sub-coderivations or sub-coterms, respectively. Note that a regular coderivation or coterm is indeed finitely presentable, e.g. as a finite directed graph, possibly with cycles, or a finite binary tree with “backpointers”.
Note that the equational theory induced by Figure 2 forms a Kleene-Herbrand-Gödel style equational specification for regular coterms (cf., e.g., [23]). This allows us to view coterms as partial recursive functionals in the standard model $\mathcal{R}$ of the appropriate type, though a full exposition is beyond the scope of this paper. Instead we will give a more formal (and, indeed, formalised) treatment of “regular” coterms and their computational interpretations in Section 3. We point the reader to the excellent book [27] for further details on models of (partial) (recursive) function(al)s.

Nonetheless, let us temporarily adopt the notation $t^{\mathcal{R}}$ for the partial functional “computed” by a coterm $t$ in $\mathcal{R}$, and present some examples, at the same time establishing some foundational results. As before, the reader may safely ignore the colouring of type occurrences in what follows. That will become meaningful later in the section.

► Example 2.4 (Extensional completeness at type 1). For any $f : \mathbb{N}^k \to \mathbb{N}$, there is a coderivation $t : \mathbb{N}^k \Rightarrow \mathbb{N}$ s.t. $t^{\mathcal{R}} = f$. To demonstrate this, we proceed by induction on $k$.

If $k = 0$ then the numerals clearly suffice. Otherwise, suppose $f : \mathbb{N} \times \mathbb{N}^k \to \mathbb{N}$ and write $f_n$ for the projection $\mathbb{N}^k \to \mathbb{N}$ by $f_n(\vec{x}) = f(n, \vec{x})$. We define the coderivation for $f$ as follows:

$$\begin{align*}
\text{cond} & \quad N \Rightarrow N \\
\text{cond} & \quad \vec{N} \Rightarrow \mathbb{N} \\
\text{cond} & \quad N, \vec{N} \Rightarrow \mathbb{N}
\end{align*}$$

where the derivations for each $f_n$ are obtained by the inductive hypothesis. It is not difficult to see that the interpretation of this coderivation in the standard model indeed coincides with $f$.

Notice that, while we have extensional completeness at type 1, we cannot possibly have such a result for higher types by a cardinality argument: there are only continuum many coderivations.

► Example 2.5 (Naïve simulation of primitive recursion). Terms of $T$ may be interpreted as coterms without the rec combinators in a straightforward manner, by the following translation:

$$\begin{align*}
\text{rec} & \quad \vec{\sigma} \Rightarrow \sigma, \vec{\sigma}, N, \sigma \Rightarrow \sigma \\
\text{cut} & \quad \vec{\sigma}, N \Rightarrow \sigma, \vec{\sigma}, N, \sigma \Rightarrow \sigma \\
\text{cond} & \quad \vec{\sigma}, N \Rightarrow \sigma, \vec{\sigma}, N \Rightarrow \sigma
\end{align*}$$

where the occurrences of $\bullet$ indicate roots of identical coderivations.

$^3$ While we may assume $k = 1 \text{ WLOG by the availability of sequence (de)coding, the current argument is both more direct and avoids the use of cuts (on non-numerals).}$
Denoting the RHS of (2) above as \( \text{rec}' \), we can check that the two sides of (2) are equivalent under Figures 2 and 3. Formally, we show \( \text{rec}' \bar{s} \bar{t} \bar{x} y = \text{rec} \bar{s} \bar{t} \bar{x} y \) by induction on \( y \):

\[
\begin{align*}
\text{rec}' \bar{s} \bar{t} 0 &= \text{cond} \bar{s} (\text{cut} (\text{rec}' \bar{s} \bar{t}) t) \bar{t} 0 \quad \text{by definition of rec' above} \\
&= \bar{s} \bar{t} \quad \text{by cond axioms} \\
&= \text{rec} \bar{s} \bar{t} \bar{x} 0 \quad \text{by rec axioms} \\
\text{rec}' \bar{s} \bar{t} \bar{x} y &= \text{cond} \bar{s} (\text{cut} (\text{rec}' \bar{s} \bar{t}) t) \bar{t} \bar{x} y \quad \text{by definition of rec' above} \\
&= \text{cut} (\text{rec}' \bar{s} \bar{t}) t \bar{x} y \quad \text{by cond axioms} \\
&= t \bar{x} y (\text{rec}' \bar{s} \bar{t} \bar{x} y) \quad \text{by cut axiom} \\
&= t \bar{x} y (\text{rec} \bar{s} \bar{t} \bar{x} y) \quad \text{by inductive hypothesis} \\
&= \text{rec} \bar{s} \bar{t} \bar{x} \bar{s} y \quad \text{by rec axioms}
\end{align*}
\]

\[\text{Example 2.6 (Turing completeness).} \] The set of regular coderivations is Turing-complete,\(^4\) i.e. \( \{t_N \mid t : N^k \Rightarrow N \text{ regular}\} \) includes all partial recursive functions on \( N \). We have already seen in Example 2.5 that we can encode the primitive recursive functions, so it remains to simulate minimisation, i.e. the operation \( \mu x (f x = 0) \), for a given function \( f \), returning the least natural number \( x \) s.t. \( f x = 0 \) (if it exists). For this, we observe that \( \mu x (f x = 0) \) is equivalent to \( H 0 \) where:

\[ H x = \text{cond} (f x) x (H sx) \] (3)

Note that \( H \) is computed by the following coderivation:

\[ \begin{array}{c}
N \Rightarrow N \\
\text{cut} \\
\hline
\text{id} N \Rightarrow N \\
\text{wk} N, N \Rightarrow N \\
N \Rightarrow N
\end{array} \] (4)

It is intuitive here to think of the blue \( N \) standing for \( x \), the red \( N \) standing for \( f(x) \), and the purple \( N \) standing for \( sx \). Again, the reader may verify that this coderivation indeed satisfies Equation (3) in the standard model \( \mathfrak{N} \). Note that we only used the type \( N \) above, and no higher-order types, so Turing-completeness holds already for \( N \)-only regular coderivations.

\[\text{Definition 2.7 (Immediate ancestry). Let t be a (co)derivation. A type occurrence \( \sigma^1 \) is an immediate ancestor\(^5\) of a type occurrence \( \sigma^2 \) in t if \( \sigma^1 \) and \( \sigma^2 \) appear in the LHSs of a premiss and conclusion, respectively, of a rule instance and have the same colour in the corresponding rule typeset in Figure 1. If \( \sigma^1 \) and \( \sigma^2 \) are elements of an indicated list, say \( \bar{\sigma} \), we also require that they are at the same position of the list in the premiss and the conclusion. Note that, if \( \sigma_1 \) is an immediate ancestor of \( \sigma_2 \), they are necessarily occurrences of the same type.}\]  

\[\text{Footnotes:} \quad \text{\footnote{For a model of program execution, we may simply take the aforementioned Kleene-Herbrand-Gödel model with equational derivability, cf. [23]. Note that this coincides with derivability by the axioms thus far presented.}} \]  

\[\text{\footnote{This terminology is standard in proof theory, e.g. as in [10].}}\]
The notion of immediate ancestor thus defined, being a binary relation, induces a directed graph whose paths will form the basis of our termination criterion.

Definition 2.8 (Threads and progress). A thread is a maximal path in the graph of immediate ancestry. A \( \sigma \)-thread is a thread whose elements are occurrences of the type \( \sigma \). We say that a \( N \)-thread progresses when it is principal for a \text{cond} step (i.e. it is the indicated blue \( N \) in the \text{cond} rule typeset in Figure 1). A (infinitely) progressing thread is a \( N \)-thread that progresses infinitely often (i.e. it is infinitely often the indicated blue \( N \) in the \text{cond} rule typeset in Figure 1.)

A coderivation is progressing if every infinite branch has a progressing thread.

Note that progressing threads do not necessarily begin at the root of a coderivation, they may begin arbitrarily far into a branch. In this way, the progressing coderivations are closed under all typing rules. Note also that arbitrary coderivations may be progressing, not only the regular ones.

Example 2.9 (Extensional completeness at type \( 1 \), revisited). Recalling Example 2.4, note that the infinite branch marked \( \cdots \) in (1) has a progressing thread along the red \( N \)s. Other infinite branches, say through \( f_0, f_1 \), etc., will have progressing threads along their infinite branches by an appropriate inductive hypothesis, though these may progress for the first time arbitrarily far from the root of (1).

As previously mentioned, we shall focus our attention in this work on the regular coderivations. Let us take a moment to appreciate some previous (non-)examples of regular coderivations with respect to the progressing criterion.

Example 2.10 (Primitive recursion and Turing-completeness, revisited). Recalling Example 2.5, notice that the RHS of (2) is a progressing coderivation: there is precisely one infinite branch (that loops on \( \bullet \)) and it has a progressing thread on the blue \( N \) indicated there.

Now recalling Example 2.6, notice that the coderivation given for \( H \) in (4) is not progressing: the only infinite branch loops on \( \bullet \) and immediate ancestry, as indicated by the colouring, admits no thread along the \( \bullet \)-loop.

One of the most appealing features of the progressing criterion is that it is decidable (for regular coderivations) by a well-known reduction to universality of Büchi automata (see, e.g., [17] for an exposition for a similar circular system). On the semantic side, we duly have:

Proposition 2.11. If \( t : \bar{\sigma} \Rightarrow \tau \) is a progressing coderivation, then \( t^\forall \) is a well-defined total functional in \((\bar{\sigma} \Rightarrow \tau)^\forall\).

Proof sketch. First, observe that each constant (i.e. rule instance) computes a total functional of corresponding type. Thus, contrapositively, if \( t^\forall \) is non-total then so is one of its immediate sub-coderivations. Continuing this reasoning yields an infinite branch \((t_i : \bar{\sigma}_i \Rightarrow \tau_i)_i \) of non-total coderivations. Now, by the progressing criterion, there must be a progressing thread \((N_i)_{i \geq k} \) along this branch. Assigning to each occurrence \( N_i \) the least natural number \( n_i \) on which \( t_i \) is non-total yields a monotone non-increasing sequence \((n_i)_{i \geq k} \) that does not converge (by definition of progressing thread), giving the required contradiction.

2.3 Some fragments and program extraction

Let us write \( T^- \) for the restriction of \( T \) to the language without the \text{rec} constants from Figure 1, and so also without the \text{rec} axioms from Figure 2.
Definition 2.12 (Circular version of \( T \)). The language of \( CT \) contains every regular progressing coderivation of \( T^{-} \) as a symbol. We identify “terms” of this language (i.e., finite applications of regular progressing coderivations, constants and variables) with coterminals in the obvious way, and call them regular progressing coterminals. \( CT \) itself is axiomatised by the schemata from Figures 2 and 3, now interpreting the metavariables \( s,t \) etc. there as ranging over (regular progressing) coterminals.

The aim of this work is to compare fragments of \( CT \) and fragments of \( T \) delineated by type level. Recall that the level of a type \( \sigma \), written \( \text{lev}(\sigma) \) is given by: \( \text{lev}(N) := 0 \) and \( \text{lev}(\sigma \rightarrow \tau) := \max(1 + \text{lev}(\sigma), \text{lev}(\tau)) \).

Definition 2.13 (Type level restricted fragments of \( T \) and \( CT \)). \( T_{n} \) is the restriction of \( T \) to the language containing only recursors \( \text{rec}_{\sigma} \) where \( \text{lev}(\sigma) \leq n \).

\( CT_{n} \) is the restriction of \( CT \) to the language containing only coderivations where all types occurring have level \( \leq n \). \( CT_{n} \) still has symbols for each constant of \( T^{-} \).

Note that this definition of \( CT_{n} \) is quite natural, since it is known that \( T_{n} \) derivations (of level \( n+1 \) functionals) can be put into an analogous form (see, e.g., [12]). For instance, the coderivation in Equation (4) has level 0 (though it is not an element of \( CT_{0} \) since it is not progressing). Note that \( CT \) itself is just the union of all \( CT_{n} \), since regular coderivations have only finitely many type occurrences and so exhibit a maximum type level.

The significance of the fragments \( T_{n} \), in terms of quantifier-restricted fragments of arithmetic, was investigated in the seminal work of Parsons [29]. Let us first recall such fragments in a two-sorted framework.

\( \text{RCA}_{0} \) is a second-order\(^{6} \) theory in the language of arithmetic (i.e. with symbols \( 0, s, +, \times, < \)). It is axiomatised by an appropriate extension of Robinson’s \( Q \) to the second-order setting, along with comprehension for (provably) \( \Delta_{1}^{0} \) predicates and induction for \( \Sigma_{1}^{0} \) formulas. A comprehensive presentation of \( \text{RCA}_{0} \) and related theories can be found in, e.g., [34, 22].

Writing \( I\Sigma_{n}^{0} \) for the induction scheme for \( \Sigma_{n}^{0} \) formulas we have:

Proposition 2.14 ([29]). If \( \text{RCA}_{0} + I\Sigma_{n+1}^{0} \vdash \forall \vec{x} \exists y A(\vec{x},y) \), where \( A \) is \( \Delta_{0}^{0} \), then there is a \( T_{n} \) term \( t \) with \( T_{n} \vdash A(\vec{x},t,\vec{x}) \).\(^{7} \)

Since we use it later, let us note that \( I\Sigma_{n}^{0} \) is equivalent, over a weak base theory (certainly \( \text{RCA}_{0} \)), to induction on Boolean combinations of \( \Sigma_{n}^{0} \) formulas, cf., e.g., [20]. The theory \( \text{ACA}_{0} \) is obtained from \( \text{RCA}_{0} \) by adding comprehension for arithmetical predicates, and is equivalent, over arithmetical theorems, to the extension of \( \text{RCA}_{0} \) by arithmetical induction.

Let us also mention a nontrivial result from previous work that we shall make use of:

Proposition 2.15 ([11]). For any regular progressing coderivation \( t \), \( \text{RCA}_{0} \) proves that \( t \) is progressing.

Since progressiveness is, a priori, a \( \Pi^{1}_{1} \) property, the above result is not at all immediate and relies on a formalisation of Büchi automaton theory that is implicit in [25]. Note that this result is “non-uniform”, in that the quantification over codervations \( t \) takes place at the meta-level. As noted in [11], the above result cannot be strengthened to a uniform one unless \( \text{RCA}_{0} \) (and so \( \text{PRA} \)) is inconsistent, by a reduction to Gödel-incompleteness.

---

\(^{6}\) As for simple type theories, all references to “second” or “higher” order are purely due to convention. Strictly speaking, these are multi-sorted first-order theories.

\(^{7}\) We assume here some standard encoding of \( \Delta_{0}^{0} \) formulas into quantifier-free formulas of \( T_{0} \). Alternatively we could admit bounded quantifiers into the language of \( T \), on which induction is allowed, without affecting expressivity. We shall gloss over this technicality here.
3 Confluence and models of $T$

We cannot formalise the standard model $\mathfrak{M}$ in arithmetic for cardinality reasons, however there are natural models of partial recursive functionals that can be formalised, namely the hereditarily recursive operations of finite type (see, e.g., [27]). We shall recast this type structure using regular coterms, in light of Example 2.6 and Example 2.10.

3.1 Reduction sequences and their logical complexity

Definition 3.1. The reduction relation $\rightsquigarrow$ on coterms is defined by orienting all the equations in Figure 2 left-to-right and taking closure under substitution and contexts. We write $\approx$ for the reflexive, symmetric, transitive closure of $\rightsquigarrow$, and freely use standard rewriting theoretic terminology and notations for these relations.

Since coterms are potentially infinite, equality for them is a $\Pi^0_1$ predicate. Thus, for the sake of simplicity, we shall henceforth deal with only regular coterms, which are finite so may be coded by natural numbers. Representing regular coterms as finite directed graphs, note that equality now reduces to checking bisimilarity, which is provably recursive in RCA$_0$.

In fact, throughout this section, we will only deal with coterms that are finite applications of regular coderivations, variables and constants (“FARs” for short). We better show that these are at least closed under reduction. To this end, let us write, for $v \in \{0,1\}^*$, $t^v$ for the sub-coterm of $t$ rooted at position $v$. We have:

Proposition 3.2 (RCA$_0$). If $s \rightsquigarrow t$ then $t$ is finitely composed of sub-coterms of $s$:

$$\exists a\text{ finite term } r(x_1, \ldots, x_n), \exists(v_1, \ldots, v_n). t = r(s_{v_1}, \ldots, s_{v_n})$$ (5)

We can take $s_{v_1}, \ldots, s_{v_n}$ to include the coderivations indicated in the contractum of a reduction, as well as the “comb” of the redex of the reduction in $s$, i.e. the siblings of all the nodes in the path leading to the redex. $r(\vec{x})$ is now the finite term induced by the contracta and this comb.

Naturally, this property also holds for $\rightsquigarrow^\ast$ and $\approx$, by $\Sigma^0_1$-induction. As a consequence:

Corollary 3.3 (RCA$_0$). If $s$ is a FAR and $s \rightsquigarrow t$ or $s \rightsquigarrow^\ast t$ or $s \approx t$, then $t$ is a FAR.

Note, in particular, that $\rightsquigarrow$, $\rightsquigarrow^\ast$ and $\approx$, restricted to FARs, are $\Sigma^0_1$-relations.

3.2 Confluence of reduction

In order to obtain basic metamathematical properties of the coterm models we later consider, we need to know that our model of computation is deterministic, so that coterms have unique interpretations. There are various ways to prove this in arithmetic, but we will approach it in terms of confluence in rewriting theory.

Throughout this subsection we continue to deal only with FARs, i.e. coterms that are finite applications of regular coderivations, variables and constants. The main goal of this subsection is to prove the following:

Theorem 3.4 (Church-Rosser, RCA$_0$). Let $t : \sigma$ be a FAR. If $t_0 \rightsquigarrow t \rightsquigarrow^\ast t_1$ then there is $t' : \sigma$ such that $t_0 \rightsquigarrow^\ast t' \rightsquigarrow t_1$. 

FSCD 2021
To some extent, we follow a standard approach to proving this result. However, since coterms are infinite (and, moreover, non-wellfounded), we must carry out our argument without appeal to induction on term structure, as is usual in presentations of arguments due to Tait and Martin-Löf (cf., e.g., [21]). Instead, we perform an argument by induction on reduction length, as in, e.g., [30].

Definition 3.5 (Parallel reduction). We define the relation $\triangleright$ on FARs as follows:
1. $t \triangleright t$ for any FAR $t$.
2. For a reduction step $r i \rightsquigarrow r(i)$, if each $t_i \triangleright t_i'$ then we have $r i \triangleright r(i')$.
3. For a reduction step $r i s s \rightsquigarrow r(i, s)$ (i.e. a rec or cond successor step), if each $t_i \triangleright t_i'$ and $s \triangleright s'$ then we have $r i s s \triangleright r(i', s')$.
4. If $s \triangleright s'$ and $t \triangleright t'$ then $s t \triangleright s' t'$.

Proposition 3.6 (RCA$_0$). $s \rightsquigarrow t \implies s \triangleright t$ and $s \triangleright t \implies s \rightsquigarrow t$.

The proof of this result is not difficult, but before giving an argument let us point out a particular consequence that we will need, obtained by $\Sigma_1^0$-induction on the length of reduction sequences:

Corollary 3.7 (RCA$_0$). $s \rightsquigarrow^* t \iff s \triangleright^* t$

Even though it is not necessary to prove the proposition above, we shall first prove the following useful lemma since we will use it later:

Lemma 3.8 (Substitution, RCA$_0$). Suppose $t \triangleright t'$. If $s \triangleright s'$ then $s[t/x] \triangleright s'[t'/x]$, for a variable $x$ of the same type as $t$ and $t'$.

Writing, say, $d : s \rightsquigarrow^* t$ for the (provably) $\Delta_1^0$ predicate “$d$ is a $\rightsquigarrow$-derivation from $s$ to $t$”, the above result is shown by proving

$$d : s \triangleright s' \implies s[t/x] \triangleright s'[t'/x]$$

by $\Sigma_1^0$-induction on the structure of the derivation $d : s \triangleright s'$. We crucially use the fact that we are dealing with FARs for the base case when $s' = s$, using a subinduction on the maximum depth of an $x$-occurrence in $s$.

Notice that Proposition 3.6 now follows immediately, by simply instantiating the Lemma above with $s = s'$ to deduce context-closure of $\triangleright$.

Lemma 3.9 (Diamond property of $\triangleright$, RCA$_0$). Suppose $t_0 < s \triangleright t_1$. Then there is some $u$ with $t_0 \triangleright u \triangleright t_1$.

Before giving the proof, it will be useful to have the following intermediate result, which follows by $\Sigma_1^0$-induction:

Proposition 3.10 (RCA$_0$). Suppose $d : r s \triangleright t$, and there is no redex in $r s$ involving $r$. There are some $i$ s.t. $t = r i$ and, for each $i$, some $d_i : s_i \triangleright t_i$ for some $d_i < d$.

The diamond property, Lemma 3.9, now follows by proving

$$\exists s'. ((d_0 : s \triangleright t_0 \text{ and } d_1 : s \triangleright t_1) \implies (t_0 \triangleright s' \text{ and } t_1 \triangleright s'))$$

by $\Sigma_1^0$-induction on $\min(|d_0|, |d_1|)$. We use Lemma 3.8 for the case when both $d_0$ and $d_1$ end by clause (2), and we use Proposition 3.10 when $d_0$ ends by clause (2) and $d_1$ ends by clause (4) or vice-versa.

---

8 Note that we really do seem to require $t \triangleright t$ for arbitrary FARs $t$, not just variables and constants, since we cannot finitely derive the former from the latter.
Proposition 3.11 (Weighted CR for $\triangleright$, RCA$_0$). If $t_0 <^m t \triangleright^n t_1$ then there is some $t'$ with $t_0 \triangleright^n t' <^m t_1$.

The argument for this follows by proving $$(d_0 : t \triangleright^n t_0 \text{ and } d_1 : t \triangleright^n t_1) \implies \exists t'(t_0 \triangleright^n t' \text{ and } d_1' : t_1 \triangleright^m t')$$ by $\Sigma^0_1$-induction on $m = |d_0|$. The following corollary is immediate:

Corollary 3.12 (CR for $\triangleright$, RCA$_0$). If $t_0 <^* t \triangleright^* t_1$ then there is $t'$ s.t. $t_0 \triangleright^* t' <^* t_1$.

We may finally conclude the main result of this subsection:

Proof of Theorem 3.4. Suppose $t_0 \leadsto^* s \leadsto^* t_1$. Then, by Corollary 3.7 we have $t_0 <^* s \triangleright^* t_1$. By Corollary 3.12 above, we have some $s'$ with $t_0 \triangleright^* s' <^* t_1$, whence $t_0 \leadsto^* s' \leadsto^* t_1$ by Corollary 3.7 again.

3.3 Hereditarily total coterms under conversion

We are now ready to present a type structure that will allow us to obtain an interpretation of $CT_n$ within $T_{n+1}$. The structure that we present in this subsection is essentially the hereditarily recursive operations of finite type, but where we adopt FARs under conversion as the underlying model of computation, cf. Example 2.6 and Example 2.10.

Definition 3.13. We define the following sets of FARs:

- $\text{HR}_N := \{ t : N \mid \exists n \in \mathbb{N}. t \approx n \}$
- $\text{HR}_{\sigma \rightarrow \tau} := \{ t : \sigma \rightarrow \tau \mid \forall s \in \text{HR}_\sigma. t s \in \text{HR}_\tau \}$

We write $\text{HR}_n$ for the union of all $\text{HR}_\sigma$ with $\text{lev}(\sigma) \leq n$.

Note that it is immediate from the definition that each $\text{HR}_\sigma$ contains only closed FARs of type $\sigma$. Notice that, by the confluence result of the previous subsection, Theorem 3.4, if $t \approx n$ then $n \in \mathbb{N}$ is unique and in fact $t \leadsto^* n$ (provably in RCA$_0$). In this way we can view every element of $\text{HR}_N$ as computing a unique natural number by means of reduction.

Fact 3.14. $\text{HR}_N$ is $\Sigma^0_1$, and if $\text{lev}(\sigma) = n > 0$ then $\text{HR}_\sigma$ is $\Pi^0_{n+1}$.

This is obtained by a (meta-level) induction on the type $\sigma$. The same induction also yields:

Proposition 3.15 (Closure properties of HR). Fix types $\sigma$ and $\tau$. RCA$_0$ proves the following:

1. If $s \in \text{HR}_\sigma$ and $t \in \text{HR}_{\sigma \rightarrow \tau}$ then $ts \in \text{HR}_\tau$. (HR closed under application)
2. If $t \in \text{HR}_\tau$ and $t \approx t'$ then $t' \in \text{HR}_\tau$. (HR closed under conversion)

Note that provability within RCA$_0$ above is non-uniform in $\sigma$ and $\tau$, i.e. RCA$_0$ proves the statements for each particular $\sigma$ and $\tau$. These properties justify defining the following type structure:

Definition 3.16 (HR structure). We write $\text{HR}$ for the type structure defined as follows:

- $\text{HR}_\sigma$ is $\text{HR}_\sigma$.
- $\text{r}_\sigma$ is just $\text{r}$. $t \in \text{HR}_\sigma$ is just $ts$.

Ultimately we will show that this structure constitutes a model of $CT_n$. For this the following lemma will be key:

Lemma 3.17 (Induction for HR, RCA$_0$). Suppose $r(x)$ and $s(x)$ are FARs. If $r(0) \approx s(0)$ and $\forall t \in \text{HR}_N. r(t) \approx s(t)$, then $\forall t \in \text{HR}_N. r(t) \approx s(t)$. 

FSCD 2021
This result is essentially “forced” by the definition of $\text{HR}_N$, reducing induction in $\text{HR}$ to induction in $\text{RCA}_0$. We also rely on the Leibniz property of equality in the structure (i.e. if $s \approx t$ and $\varphi(s)$ then $\varphi(t)$), which is facilitated by the symmetry and transitivity of $\approx$.

Note that the axioms governing the constants are immediately given that our reduction relation is obtained from them. The remaining number-theoretic axioms follow from confluence (for $\neg s \approx 0$, by uniqueness of normal forms) and the fact that no reduction rule has $s$ at the head (for $ss \approx st$ implies $s \approx t$, requiring a $\Sigma^0_1$-induction).

Thus to conclude that $\text{HR}$ actually constitutes a model of $T$ (or $CT$) it remains to show that it interprets each term $t$ of $T$ (or coterm of $CT$), i.e. that indeed $t \in \text{HR}$. For $T$, this follows from Tait’s seminal normalisation result [36]:

**Proposition 3.18.** $\text{HR}$ is a model of $T$.

In fact this result can be formalised non-uniformly in the following sense: for each term $t$ of type $\tau$ with $\text{lev}(\sigma) \leq n$, we have $\text{RCA}_0 + ISigma^0_{n+2} \vdash HR_2(t)$. We will see a similar situation for membership of $CT_n$ coterms in $\text{HR}_{n+1}$ later, but with the quantifier complexity of induction increased by 1.

### 4 Interpretation of $CT$ into $T$

In this section we show that the type structure $\text{HR}$ introduced in the previous section indeed constitutes a model of $CT$. In fact, we will formalise the membership of $CT_n$ coterms in $\text{HR}_{n+1}$ within the theory $\text{RCA}_0 + ISigma^0_{n+2}$ (non-uniformly), whence we obtain explicit equivalent terms of $T_{n+1}$ by program extraction. Throughout this section we continue to work only with regular coterms that are finite applications of coderivations, variables and constants (i.e. FARs).

#### 4.1 Canonical branches of non-total coterms

In this section we give a formalised proof of the totality of $CT$-coterms. Our approach will be to import a suitable version of the proof of Proposition 2.11 but relativise all the quantifiers, there in the standard model, to their respective domains in $\text{HR}$.

First let us note that $\text{HR}$ is closed under the typing rules of $CT$:

**Observation 4.1.** Consider a rule instance $\tilde{\sigma}_0 \Rightarrow \tau_0 \quad \ldots \quad \tilde{\sigma}_k \Rightarrow \tau_k$ for some $k < 2$. If $t_i \in HR_{\tilde{\sigma}_i \rightarrow \tau}$, for $i < k$ then $t_0 \ldots t_k \in HR_{\tilde{\sigma} \rightarrow \tau}$.

This follows by simple inspection of the rules of $CT$. By contraposition, any coderivation $\notin HR$ must induce an infinite branch of coderivations $\notin HR$, similarly to the proof of Proposition 2.11. The next definition formalises a canonical such branch, as induced by an input on which a coderivation is non-hereditarily-total. We shall present just the definition of the branch first, and then argue that it is well-defined, for each explicit $CT_n$ coderivation, in $\text{RCA}_0 + ISigma^0_{n+2}$.

**Definition 4.2** (Branch generated by a non-total input). Let $t_0 : \tilde{\sigma}_0 \Rightarrow \tau_0$ be a coderivation and let $\tilde{s}_0 \in HR_{\tilde{\sigma}_0}$ s.t. $t_0 \tilde{s}_0 \notin HR_\tau$. We define the branch $(t_i : \tilde{\sigma}_i \Rightarrow \tau_i)_{i \geq 0}$ and inputs $\tilde{s}_i \in HR_{\tilde{\sigma}_i}$, generated by $t_0$ and $\tilde{s}_0$ below. Each rule instance is as typeset in Figure 1, with immediate sub-coderivations $t$ and $t'$ respectively. Furthermore, we preserve the invariant $t_i \tilde{s}_i \notin HR_{\tau_i}$ throughout the definition.
1. (t_i cannot be an initial sequent).
2. Suppose t_i ends with wk and \( s_i = (\bar{s}, s) \). Then \( t_{i+1} := t \) and \( \bar{s}_{i+1} := \bar{s} \).
3. Suppose t_i ends with ex and \( s_i = (r, r, s, \bar{s}) \). Then \( t_{i+1} := t \) and \( \bar{s}_{i+1} := (r, s, r, \bar{s}) \).
4. Suppose t_i ends with cntr and \( s_i = (\bar{s}, \bar{s}) \). Then \( t_{i+1} := t \) and \( \bar{s}_{i+1} := (\bar{s}, s, \bar{s}) \).
5. Suppose t_i ends with cut and \( s_i = \bar{s} \). Then if \( t \bar{s} \in \text{HR}_\sigma \) then \( t_{i+1} := t' \) and \( \bar{s}_{i+1} := (\bar{s}, t \bar{s}) \).
6. Otherwise, \( t_{i+1} := t \) and \( \bar{s}_{i+1} := \bar{s} \).
7. Suppose t_i ends with L and \( s_i = (\bar{s}, s) \). If \( t \bar{s} \in \text{HR}_\rho \) then \( t_{i+1} := t' \) and \( \bar{s}_{i+1} := (\bar{s}, t (t \bar{s}) ) \).
8. Otherwise, \( r = n_0 \), then \( t_{i+1} := t \) and \( \bar{s}_{i+1} := \bar{s} \).

The main result of this subsection is:

**Proposition 4.3.** Let \( t_0 : \delta_0 \Rightarrow \tau_0 \) be a fixed coderivation in which all types occurring have level \( \leq n \). \( \text{RCA}_0 + \Sigma_{n+2}^0 \) proves the following: if \( \bar{s}_0 \in \text{HR}_{\delta_0} \) s.t. \( t_0 \bar{s}_0 \notin \text{HR}_{\tau_0} \) then the branch \( (t_i)_{i \in \mathbb{N}} \) and inputs \( (s_i)_{i \in \mathbb{N}} \) generated by \( t_0 \) and \( \bar{s}_0 \) are \( \Delta_{n+2}^0 \)-well-defined.

Most of the cases follow by the inductive hypothesis and the closure of \( \text{HR} \) under \( \approx \). Crucially, for the \( R \) case, we must use the \( \Sigma_{n+1}^0 \)-minimisation principle, a consequence of \( I \Sigma_{n+1}^0 \) cf. [20], to find the “least” \( \text{FAR} \) \( s \) satisfying a \( \Sigma_{n+1}^0 \) property. We also use confluence to ensure that the cond-case is well-defined.

### 4.2 Progressing coterms are hereditarily total

We are now ready to show that \( CT \)-coterms are hereditarily total, i.e. that they belong to \( \text{HR} \).

Now that we have formalised the infinite “non-total” branches of the proof of Proposition 2.11, relativised to the type structure \( \text{HR} \), we continue to formalise the remainder of the argument. First, again by confluence, we have:

**Lemma 4.4 (RCA_0).** Let \( t_0 : \delta_0 \Rightarrow \tau_0 \) and \( s_0 \in \text{HR}_{\delta_0} \) be a coderivation and inputs s.t. \( t_0 \bar{s}_0 \notin \text{HR}_{\tau_0} \). Furthermore let \( t_i : \delta_i \Rightarrow \tau_i \) and \( s_i \in \text{HR}_{\delta_i} \) be a branch and inputs generated by \( t_0 \) and \( \bar{s}_0 \) satisfying Definition 4.2.

Suppose some \( N \)-occurrence \( N_{i+1} \in \delta_{i+1} \) is an immediate ancestor of some \( N \)-occurrence \( N_i \in \delta_i \). Write \( s_i \in \bar{s}_i \) for the coterms in \( \text{HR}_N \) corresponding to \( N_i \), and similarly \( s_{i+1} \in s_{i+1} \) for the coterms \( s_{i+1} \in \text{HR}_N \) corresponding to \( N_{i+1} \). If \( s_i \approx s_{i+1} \approx n \), then:

1. \( n_i \geq n_{i+1} \).
2. If \( N_i \) is principal for a cond step, then \( n_i > n_{i+1} \).

In order to complete our formalisation of the totality argument, we actually have to use an “arithmetical approximation” of thread progression that nonetheless suffices for our purposes, similarly to [11]. The reason for this is that, even though non-total branches are well-defined by Proposition 4.3, we do not a priori have access to them as sets in extensions of \( \text{RCA}_0 \) by induction principles, and so the lack of progressing threads along them does not directly contradict the fact that a coderivation is progressing.\(^9\)

\(^9\) Recall that, strictly speaking, we assume all our objects are coded by natural numbers in the ambient theory (here fragments of second-order arithmetic). Thus we may always find a “least” object satisfying a property when one exists. Naturally this will correspond to a form of induction in the proof of well-definedness.

\(^{10}\) Notice that this is not an issue in the presence of arithmetical comprehension, i.e. in \( \text{ACA}_0 \), but in that case logical complexity of defined sets is not a stable notion: all of arithmetical comprehension reduces to \( \Pi^0_1 \)-comprehension.
Proposition 4.5 (RCA0). Suppose \( \vec{t}_i \) and \( \vec{s}_i \) are as in Lemma 4.4. Any \( N \)-thread along \((t_i)_i\) is not progressing. Moreover, \( \forall k \exists m \), any \( N \)-thread from \( t_k \) progresses \( \leq m \) times.

The main result of this subsection is:

Theorem 4.6. Let \( t : \vec{\sigma} \Rightarrow \tau \) be a \( CT_n \)-coderivation. Then \( RCA_0 + I\Sigma^0_{n+2} \vdash t \in HR_{\vec{\sigma} \Rightarrow \tau} \).

As well as using Proposition 4.5, this result relies crucially on the fact that we prove that \( CT \)-coderivations progress in \( RCA_0 \), Proposition 2.15 (itself from [11], allowing us to “substitute” the \( \Delta^0_{n+2} \)-definition of a non-hereditarily-total branch from Definition 4.2 to obtain an argument using \( I\Sigma^0_{n+2} \) overall.

Corollary 4.7. \( HR \) is a model of \( CT \).

4.3 Interpretation of \( CT_n \) into \( T_{n+1} \)

We may now realise our model-theoretic results as bona fide interpretations of fragments of \( CT \) into fragments of \( T \). As a word of warning, coterms of \( CT \) in this section, when operating inside \( T \), should formally be understood by their Gödel codes, i.e. in this section \( T \) is “one meta-level higher” than \( CT \). Until now we have been formalising the metatheory of \( CT \) within second-order arithmetic, and so arithmetising its syntax as natural numbers. Since we will here invoke program extraction from these fragments of arithmetic to fragments of \( T \) to interpret \( CT \), the same coding carries over. At the risk of confusion, we shall suppress this formality henceforth.

Theorem 4.8. If \( CT_n \vdash s = t \) then \( T_{n+1} \vdash s \approx t \).

The main idea here is that our formalisation of the \( HR \) model within arithmetic allows us to prove the following reflection principle in \( RCA_0 + I\Sigma^0_2 \):

\[ \forall P \text{ (if } P \text{ is a } CT_n \text{ proof of } s = t \text{ then } \exists d : s \approx t) \]

Since this statement is \( \Pi^0_2 \), we may apply program extraction, Proposition 2.14, to indeed witness the required derivation \( d \) within \( T_{n+1} \), as required.

Corollary 4.9. If \( t : \vec{N} \Rightarrow N \) is a progressing coterm of \( CT_n \), then there is a \( T_{n+1} \)-term \( t : \vec{N} \Rightarrow N \) such that \( t^{OR} = t^{\bar{OR}} \).

5 Further results

In this section we shall give some further rewriting-theoretic results related to the system \( CT \) we have presented.

5.1 Continuity at type 2

It is well-known that the type 2 functionals of \( T \) are continuous, in the sense that any type 1 function input is only queried a finite number of times, e.g. [38, 32, 39]. For the case of \( CT \), we may actually formalise a variation of the classical argument of [38] within second-order arithmetic, extending the simulation of \( CT \) coterms within \( T \) to type 2 functionals. For the sake of brevity, we shall not refine our exposition by type level in this subsection.

Let us fix a \( CT \) coderivation \( t : \vec{\sigma} \Rightarrow N \) s.t. each \( \sigma_i = N_1 \rightarrow \cdots \rightarrow N_{k_i} \rightarrow N \), and let us henceforth work in \( ACA_0 \), distinguishing second-order variables \( f_i : N^{k_i} \rightarrow N \), intuitively representing the inputs for \( t \). Within \( CT \), introduce new (uninterpreted) constant symbols \( f_i : N_1 \rightarrow \cdots \rightarrow N_{k_i} \rightarrow N \) for each \( \sigma_i \), and new reduction steps:

\[
\bigwedge_{i=1}^{k_i} \vec{u}_i \rightarrow f_i(\vec{u}_1, \ldots, \vec{u}_{k_i})
\]
Notice that reduction is now still semi-recursive in the oracles \( \vec{f} \), i.e. \( \rightsquigarrow, \rightsquigarrow^* \approx \) are now \( \Sigma_1^0(\vec{f}) \).

To save the effort of reproving our confluence results from Section 3 with these new oracle symbols, we shall simply henceforth assume a suitable consistency principle:

\[
\text{UNF}_N : \forall m, n. (m \approx n \supset m = n)
\]

Note that, since this is a true \( \Pi_1^0 \) statement (by meta-level reasoning), it carries no computational content and adding it to \( \text{ACA}_0 \) still admits extraction into \( T \) (see, e.g., [24]).

From here, we define \( \text{HR}_N^\vec{f} \) just as \( \text{HR}_\sigma \), but allowing coterms to include the symbols \( \vec{f} \). Since each \( \text{HR}_\sigma \) is arithmetical in \( \rightsquigarrow \), we have that each \( \text{HR}_N^\vec{f} \) is arithmetical in our extended reduction relation, so with free second-order variables \( \vec{f} \). Note in particular that we have that each \( f_i \in \text{HR}_N^\vec{f} \), thanks to (6) above. By adapting our approach from Section 4, we may show:

\[\text{Theorem 5.1 (ACA}_0 + \text{UNF}_N). \forall \vec{f}. \exists t \vec{f} \in \text{HR}_N^\vec{f}\]

Expanding out this result we have that \( \text{ACA}_0 + \text{UNF}_N \vdash \forall \vec{f}. \exists n. t \vec{f} \approx n \). Note that this yields the required syntactic continuity property: since any \( \approx \)-sequence is finite, we may compute \( t(\vec{f}) \) by querying each \( f_i \) only finitely many times. From here, by applying a relativised version of program extraction (see, e.g., [24]), we obtain a strengthening of our simulation of \( \text{CT} \)-coterms by \( T \) terms to type 2 (stated without refinement to type level):

\[\text{Corollary 5.2. If } t \text{ is a level 2 coterm of } \text{CT}, \text{ then there is a } T \text{ term } t' \text{ s.t. } t^{\text{SN}} = t'^{\text{SN}}.\]

5.2 A “term model” à la Tait and strong normalisation

It is an immediate consequence of our results that \( \text{CT} \)-coterms are weakly normalising. Namely, by an induction on type (using confluence for the base case, at type \( N \)), we may show that each \( t \in \text{HR} \) is weakly normalising. Thus, by Theorem 4.6, we have:

\[\text{Proposition 5.3. Each closed } \text{CT} \text{ coterm is weakly normalising. Moreover, any } \text{CT}_n \text{ coterm is provably weakly normalising inside } \text{RCA}_0 + I \Sigma_n^0 + 2.\]

In this section we will go further and show that \( \text{CT} \)-coterms are actually strongly normalising, just like \( T \)-terms. For the sake of brevity, we will not formalise our exposition within arithmetic. We will define a minimal “coterm model” in a similar way to Tait’s term models of system \( T \) [36]. This is complementary to our development of \( \text{HR} \): while that structure was an “over-approximation” of the language of \( \text{CT} \), the structure we are about to define is an “under-approximation”, by virtue of its definition. Naturally, the point is to show that the approximation is, in fact, tight.

\[\text{Definition 5.4 (Convertibility). We define the following sets of closed } \text{CT} \text{-coterms:}\]

\[C_N := \{ t : N \mid t \text{ is strongly normalising} \},\]

\[C_{\sigma \rightarrow \tau} := \{ t : \sigma \rightarrow \tau \mid \forall s \in C_\sigma. ts \in C_\tau \}.\]

By an induction on type, we establish suitable versions of Proposition 3.15 and the normalisation property for \( C \):

\[\text{Proposition 5.5. We have the following:}\]

1. If \( t \in C_{\sigma \rightarrow \tau} \) and \( s \in C_\sigma \) then \( ts \in C_\tau \). (\( C \) closed under application)
2. If \( t \in C_\tau \) and \( t \rightsquigarrow t' \) then \( t' \in C_\tau \). (\( C \) closed under reduction)
3. If \( t \in C_\tau \) then \( t \) is strongly normalising. (\( C \subseteq \text{SN} \))

\[\text{The drawback of this approach is that it does not yield any bona fide interpretation of } \text{CT} \text{ into } T, \text{ which is why we chose to formalise a confluence argument for our main interpretation result.}\]
Closure of \( \rightsquigarrow \) under contexts is required for 2 and 3. Note that the strong normalisation condition for \( C_N \) is crucial to justify closure under reduction, (2), at base type \( N \). In contrast, for \( HR_N \) we only asked for conversion to a numeral, and so the analogous property of closure under conversion was a consequence of symmetry.

Let us call a coterm \( t \) neutral if, for any \( s \), any redex of \( ts \) is either entirely in \( t \) or entirely in \( s \). We also have the following expected characterisation of convertibility by induction on type:

\[\text{Lemma 5.6 (Convertibility lemma). Let } t \text{ be neutral. If } \forall t' \rightsquigarrow t, t' \in C_\tau, \text{ then } t \in C_\tau.\]

As for classical proofs of strong normalisation for \( T \), we must also make use of a sub-induction on the size of the complete reduction trees of elements of \( C \); recall that they are strongly normalising, by Proposition 5.5, and so have finite reduction trees by König’s lemma,\(^\text{12}\) since there are always only finitely many redexes.

Now we can go on to define a non-converting branch, just like we did for the standard model \( \mathcal{M} \) in Proposition 2.11 (non-total branch), and for \( HR \) in Definition 4.2 (non-hereditarily-total branch). As in the latter case, we need to prove well-definedness of such a branch, cf. Observation 4.1 and Proposition 4.3.

\[\text{Proposition 5.7 (Preservation of convertibility). Let } \vec{r} \in C_\vec{\rho} \text{ and } \vec{s} \in C_\vec{\sigma}. \text{ We have:}\]

\[\begin{align*}
\text{If } s &\in C_\sigma \text{ then } \exists \vec{s} \in C_{\vec{\sigma}}. \\
\text{If } r &\in C_\rho, s \in C_\sigma \text{ and } t \vec{r} \vec{s} \vec{r} \vec{s} \in C_\tau \text{ then } \text{ext} \vec{r} \vec{s} \vec{r} \vec{s} \in C_\tau. \\
\text{If } s &\in C_\rho \text{ and } t \vec{s} \in C_\tau \text{ then } \text{wkt} \vec{s} \vec{s} \in C_\tau. \\
\text{If } s &\in C_\rho \text{ and } t \vec{s} \vec{s} \vec{r} \vec{s} \in C_\tau \text{ then } \text{cntr} t \vec{s} \vec{s} \vec{r} \vec{s} \in C_\tau. \\
\text{If } t_0 \vec{s} &\in C_\rho \text{ and } \forall s \in C_\sigma, t_1 \vec{s} s \in C_\tau \text{ then } \text{cut} t_0 t_1 \vec{s} \in C_\tau. \\
\text{If } r &\in C_\rho \text{ and } t_0 \vec{s} \in C_\rho \text{ and } \forall s \in C_\sigma, t_1 \vec{s} s \in C_\tau \text{ then } \text{L} t_0 t_1 \vec{s} \vec{r} \vec{s} \in C_\tau. \\
\text{If } \forall s &\in C_\sigma, t \vec{s} s \in C_\tau \text{ then } \text{R} t \vec{s} \in C_{\sigma \rightarrow \tau}. \\
0 &\in C_N.
\end{align*}\]

This is proved by an induction on the reduction trees of \( \vec{s}, \vec{s}, \vec{r}, \vec{r} \) (which, again, are strongly normalising), in most cases appealing directly to the convertibility lemma above. For the \( L \) case we rely on closure of \( C \) under application, cf. Proposition 5.5, and for the \( R \) case we must employ a sub-induction on the reduction tree of an input \( s \in C_\sigma \).

As a consequence of our results in Sections 3 and 4, observe that any \( s \in C_N \) reduces to a unique numeral. This is because \( C_N \) contains only CT-coterms, by definition, which are weakly normalising and confluent. From here we may establish the main result of this subsection:

\[\text{Theorem 5.8 (Convertibility for CT). Any CT-coderivation } t : \vec{\sigma} \Rightarrow \tau \text{ is in } C_{\vec{\sigma} \rightarrow \tau}.\]

The proof constructs a “non-converting” branch similarly to Definition 4.2 (or the proof of Proposition 2.11). There is one subtlety, however, in the treatment of the cond case, requiring the uniqueness of normal forms for elements of \( C_N \). We obtain the required inputs for the premiss occurrences of \( N \) by an induction on the reduction tree of an input of the conclusion occurrence.

\(^{12}\) Note that König’s lemma is equivalent to arithmetical comprehension, i.e. ACA\( _0 \), already over RCA\( _0 \) (cf., e.g., [34]).

\(^{13}\) All rules have type as presented in Figure 1.
Since \( \mathcal{C} \) is closed under application, Proposition 5.5, we inherit \( \mathcal{C} \) membership for all \( \text{CT} \)-coterms. Since elements of \( \mathcal{C} \) are strongly normalising, again Proposition 5.5, and since reduction is confluent, Theorem 3.4, we finally have:

▶ Corollary 5.9 (Strong normalisation for \( \text{CT} \)). Any closed \( \text{CT} \) coterm strongly normalises to a unique normal form.

6 Conclusions

In this work we gave an interpretation of a theory of level \( n \) circular derivations (\( \text{CT}_n \)) into level \( n + 1 \) \( \text{T}_{n+1} \) (\( \text{T}_{n+1} \)), by formalising models of \( \text{CT} \) within fragments of arithmetic and applying program extraction. This result is optimal by a converse result from parallel work [12]. In particular, \( \text{CT}_n \) and \( \text{T}_{n+1} \) are equi-consistent. We also showed confluence, strong normalisation, and continuity at type 2 for \( \text{CT} \)-coterms.

In future work it would be interesting to establish results on Curry-Howard aspects of our underlying type systems, establishing forms of cut-elimination and relationships with infinitary lambda-calculi. Ideas from [4, 15, 3] may prove useful to this effect.

References

Further material for Section 4

Proof of Proposition 4.3. Let us write $Gen(i,(t_0,\bar{s}_0),(t_i,\bar{s}_i))$ for “$t_i$ and $\bar{s}_i$ are the $i^{th}$ sequent and input tuple generated by $t_0$ and $\bar{s}_0$.” Notice that the construction of $t_i$ and $\bar{s}_i$ itself is recursive in $HR_{n+1}$, $t_0$ and $\bar{s}_0$, and so $Gen$ is certainly recursion-theoretically $\Delta^0_{n+2}(t_0,\bar{s}_0)$, by appealing to Fact 3.14. To formally prove that $Gen$ is $\Delta^0_{n+2}$ inside our theory, it suffices to show determinism:

$$\forall i, \forall (t_i,\bar{s}_i),(t'_i,\bar{s}'_i). \left( Gen(i,(t_0,\bar{s}_0),(t_i,\bar{s}_i)) \land Gen(i,(t_0,\bar{s}_0),(t'_i,\bar{s}'_i)) \implies t_i = t'_i \land \bar{s}_i = \bar{s}'_i \right)$$

Writing $Gen$ syntactically as a $\Sigma^0_{n+2}$ formula, the above may be directly proved by $\Pi^0_{n+2}$-induction on $i$, appealing to the cases of Definition 4.2 above.

It remains to show that the construction is total, i.e. that each $(t_i,\bar{s}_i)$ actually exists. In fact we will simultaneously prove this and the inductive invariant of the construction, so the formula,

$$\exists (t_i,\bar{s}_i). (Gen(i,(t_0,\bar{s}_0),(t_i,\bar{s}_i)) \land t_i \bar{s}_i \notin HR_{n+1})$$

(7)
by induction on $i$. Note that, since $\text{lev}(\tau_i) \leq n$ we have that $HR_{\tau_i}$ is $\Pi^{0}_{n+1}$ by Fact 3.14, and so $t_i\bar{s}_i \not\in HR_{\tau_i}$ is $\Sigma^0_{n+1}$, whereas Gen$(i,(t_0,\bar{s}_0),(t_i,\bar{s}_i))$ is $\Delta^0_{n+2}$ as already mentioned. Thus the inductive invariant in (7) is indeed $\Sigma^0_{n+2}$.

First, to justify (1), let us consider the possible initial sequents:

- For the 0 rule: we have $0 \in HR_{\Lambda}$ by definition;
- For the $s$ rule: if $t \in HR_{\Lambda}$, then $t \approx n$ for some $n \in \mathbb{N}$, by definition of $HR_{\Lambda}$, and so also $st \approx s_0$, by closure of $\approx$ under contexts. Hence $st \in HR_{\Lambda}$.
- For an $id_s$ rule: if $s \in HR_{\sigma}$ then $id \approx s$ by $id$ reduction. Hence $id \in HR_{\sigma}$.

Now, the base case, for $i = 0$, follows by the assumption on $t_0$ and $\bar{s}_0$, so let us assume that Gen$(i,(t_0,\bar{s}_0),(t_i,\bar{s}_i))$ and $t_i\bar{s}_i \not\in HR_{\tau_i}$. We will witness the existential of the inductive invariant with the coderivation $t_{i+1}$ and inputs $\bar{s}_{i+1}$ as given in Definition 4.2 above (justifying their existence when necessary), showing $t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}}$. We shall also adopt the same notation for inputs and types as in Definition 4.2.

For (2), the wk case, we have:

$$t_i\bar{s}_i \not\in HR_{\tau_i} \quad \therefore \quad wk \ t \bar{s} \ \not\in HR_{\tau_i} \quad \text{by inductive hypothesis}$$
$$t \bar{s} \not\in HR_{\tau_i} \quad \text{by } \sim_{wk} \text{ and closure of } HR_{\tau_i} \text{ under } \approx$$
$$t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}} \quad \text{by definitions}$$

For (3), the ex case, we have:

$$t_i\bar{s}_i \not\in HR_{\tau_i} \quad \therefore \quad ex \ t \bar{r}s \bar{s} \not\in HR_{\tau_i} \quad \text{by definitions}$$
$$t \bar{r}s \bar{s} \not\in HR_{\tau_i} \quad \text{by } \sim_{ex} \text{ and } \therefore \text{ HR } \text{ closed under } \approx$$
$$t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}} \quad \text{by definitions}$$

For (4), the cntr case, we have:

$$t_i\bar{s}_i \not\in HR_{\tau_i} \quad \therefore \quad cntr \ t \bar{s}s \not\in HR_{\tau_i} \quad \text{by definitions}$$
$$t \bar{s}s \not\in HR_{\tau_i} \quad \text{by } \sim_{cntr} \text{ and } \therefore \text{ HR } \text{ closed under } \approx$$
$$t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}} \quad \text{by definitions}$$

For (5), the cut case, assume without loss of generality that $t \bar{s} \in HR_{\tau_i}$. We have:

$$t_i\bar{s}_i \not\in HR_{\tau_i} \quad \therefore \quad cut \ t \bar{t}'\bar{s} \not\in HR_{\tau_i} \quad \text{by definitions}$$
$$t \bar{t}'\bar{s} \not\in HR_{\tau_i} \quad \text{by } \sim_{cut} \text{ and } \therefore \text{ HR } \text{ closed under } \approx$$
$$t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}} \quad \text{by definitions}$$

For (6), the L case, assume without loss of generality that $t \bar{s} \in HR_{\tau_i}$, and so also $s(t \bar{s}) \in HR_{\tau_i}$ by Proposition 3.15. We have:

$$t_i\bar{s}_i \not\in HR_{\tau_i} \quad \therefore \quad L \ t \bar{t}'\bar{s}s \not\in HR_{\tau_i} \quad \text{by definitions}$$
$$t \bar{t}'\bar{s}s \not\in HR_{\tau_i} \quad \text{by } \sim_{L} \text{ and } \therefore \text{ HR } \text{ closed under } \approx$$
$$t_{i+1}\bar{s}_{i+1} \not\in HR_{\tau_{i+1}} \quad \text{by definitions}$$
For (7), the $R$ case, we have:

\[
\begin{align*}
& t_i \vec{s}_i \notin HR_{r_i} \quad \text{by inductive hypothesis} \\
& \therefore \ R \vec{s} \notin HR_{\sigma \rightarrow \tau} \quad \text{by definitions} \\
& \therefore \ \exists \vec{s}' \in HR_{\sigma \rightarrow \tau}. R t \vec{s} \vec{s}' \notin HR_{\tau} \quad \text{by definition of } HR_{\sigma \rightarrow \tau} \\
& \therefore \ \exists \vec{s}' \in HR_{\sigma \rightarrow \tau}, t \vec{s} \vec{s}' \notin HR_{\tau} \quad \text{by } \sim_R \text{ and } \therefore HR_{\tau} \text{ closed under } \approx \\
& \therefore \ t \vec{s} \notin HR_{\tau} \quad \therefore s \text{ is well-defined by } \Sigma_{n+1}^0-\text{minimisation} \\
& \therefore \ t_{i+1} \vec{s}_{i+1} \notin HR_{r_{i+1}} \quad \text{by definitions}
\end{align*}
\]

In the penultimate step, note that we have from the inductive hypothesis $\exists s (s \in HR_{\sigma} \land t \vec{s} \vec{s} \notin HR_{\tau})$, where $\text{lev}(\sigma) < n$ and $\text{lev}(\tau) \leq n$. Thus $(s \in HR_{\sigma} \land t \vec{s} \vec{s} \notin HR_{\tau})$ is indeed $\Sigma_{n+1}^0$, by Fact 3.14, and so $\Sigma_{n+1}^0-\text{minimisation}$ applies.

For (8), the $\text{cond}$ case, note by the inductive hypothesis we have $r \in HR_N$ so by definition of $HR_N$ and confluence, we have that $r$ converts to a unique numeral. Thus the two cases considered by the definition of $t_{i+1}$ and $\vec{s}_{i+1}$ are exhaustive and exclusive, and we consider each separately.

If $r \approx 0$ then we have:

\[
\begin{align*}
& t_i \vec{s}_i \notin HR_{r_i} \quad \text{by inductive hypothesis} \\
& \therefore \ \text{cond } t t' \vec{s} \vec{r} \notin HR_{r} \quad \text{by definitions} \\
& \therefore \ \text{cond } t t' \vec{s} \vec{r} \notin HR_{r} \quad \text{by assumption and } \therefore HR_{\tau} \text{ closed under } \approx \\
& \therefore \ t \vec{s} \notin HR_{r} \quad \therefore cond \text{ and } \therefore HR_{\tau} \text{ closed under } \approx \\
& \therefore \ t_{i+1} \vec{s}_{i+1} \notin HR_{r_{i+1}} \quad \text{by definitions}
\end{align*}
\]

If $r \approx s_n$ then we have:

\[
\begin{align*}
& t_i \vec{s}_i \notin HR_{r_i} \quad \text{by inductive hypothesis} \\
& \therefore \ \text{cond } t t' \vec{s} \vec{r} \notin HR_{r} \quad \text{by definitions} \\
& \therefore \ \text{cond } t t' \vec{s} \vec{s}_n \notin HR_{r} \quad \text{by assumption and } \therefore HR_{\tau} \text{ closed under } \approx \\
& \therefore \ t \vec{s} \vec{n} \notin HR_{r} \quad \therefore cond \text{ and } \therefore HR_{\tau} \text{ closed under } \approx \\
& \therefore \ t_{i+1} \vec{s}_{i+1} \notin HR_{r_{i+1}} \quad \text{by definitions}
\end{align*}
\]

This concludes the proof.

Proof of Proposition 4.5. We shall prove only the “moreover” clause, the former following a fortiori. First, suppose we have a (finite) $N$-thread $(N^1)^l_{i=0}$ beginning at $t_k$. Let $s_i \in \vec{s}_i$ be the corresponding input of $N^1$ for $1 \leq i \leq l$, and let each $r_i \approx \vec{n}_i$, for unique $n_i \in \mathbb{N}$, by definition of $HR_N$ and confluence. Letting $m$ be the number of times that $(N^1)^l_{i=1}$ progresses, we may show by induction on $l$ that $n_l \leq n_k - m$, using Lemma 4.4 for the inductive steps.

Now, to prove the “moreover” statement, fix some $k$ and let $N^k \subseteq \vec{s}_k$ exhaust the $N$ occurrences in $\vec{s}_k$. Let $\vec{r}_k \subseteq \vec{s}_k$ be the corresponding inputs, and write $\vec{n}_k$ for the unique natural numbers such that each $r_{ki} \approx n_{ki}$, by definition of $HR_N$ and confluence. We may now simply set $m := \max \vec{n}_k$, whence no thread from $t_k$ may progress more than $m$ times by the preceding paragraph.

Proof of Theorem 4.6. First, by Proposition 2.15 (from [11]), we have that $\text{RCA}_0$ proves that $t$ is progressing. Consequently $\text{RCA}_0$ proves that, for any branch $(t_i)_l$, there is some $k$ s.t. there are arbitrarily often progressing finite threads beginning from $t_k$:

\[
\exists k. \forall m . \text{ there is a (finite) } N \text{-thread from } t_k \text{ progressing } > m \text{ times}
\] (8)

\footnote{The argument for this is similar to that of Proposition 6.2 from [11].}
Note that this statement is purely arithmetical in \((t_i)_i\) and so, if \((t_i)_i\) is \(\Delta^0_{n+2}\)-well-defined, then in fact RCA_0 + \(I\Sigma^0_{n+2}\) proves (8), by conservativity over \(I\Sigma^0_{n+2}((t_i)_i)\) and then substitution of the \(\Delta^0_{n+2}\)-definition of \((t_i)_i\).

Now, working inside RCA_0 + \(I\Sigma^0_{n+2}\), suppose for contradiction that \(\vec{s} \in \text{HR}_\vec{f} s.t. \ t \vec{s} \notin \text{HR}_\vec{f}\).

By Proposition 4.3, we can \(\Delta^0_{n+2}\)-well-define the branch \((t_i)_i\), generated by \(t\) and \(\vec{s}\). Thus we indeed have (8), contradicting Proposition 4.5.

Proof sketch of Theorem 4.8. Let us work inside RCA_0 + \(I\Sigma^0_{n+2}\). By Theorem 4.6 we have that \(s, t \in \text{HR}_\vec{f}\), so suppose that \(CT_n \vdash s = t\) (which is a \(\Sigma^0_1\) relation). Now, invoking Lemma 3.17 and by verifying the other axioms for FARs in general, we indeed have that \(s \equiv t\), by \(\Sigma^0_1\)-induction on the \(CT_n\) proof of \(s = t\).

Now, invoking the extraction theorem, Proposition 2.14, for the above paragraph, we can extract a \(T_{n+1}\)-term \(d(\cdot)\) witnessing the following “reflection” principle:

\[
T_{n+1} \vdash \text{“} P \text{ is a } CT_n \text{ proof of } s = t \text{” } \supset d(P): s \equiv t
\]

We may duly substitute a concrete \(CT_n\) proof \(P\) of \(s = t\) into the above principle to conclude that \(T_{n+1} \vdash s \equiv t\), as required.

\section*{B Further material for Section 5}

Proof sketch of Theorem 5.1. The argument is essentially the same as that for Theorem 4.6. Assuming otherwise, for contradiction, we may generate a non-hereditarily-total branch just as in Definition 4.2, and its well-definedness is shown just as in Proposition 4.3. Note that all induction/minimisation used is in fact arithmetical in \(\prec\) and \(\text{HR}_\vec{f}\), so the branch is indeed \(\Delta^0_{n+2} (\vec{f})\)-well-defined (for \(n\) the maximal type level in \(t\)).

Since we no longer concern ourselves with the refinement of type levels, the remainder of the argument is actually simpler than that of Section 4. Instead of dealing with the arithmetical approximation of progressiveness, we may immediately access the generated non-total branch as a set, thanks to the availability of arithmetical comprehension in ACA_0.

We also have a suitable version of Lemma 4.4 for \(\text{HR}_\vec{f}\), this time using UNF_N instead of confluence, and so the appropriate contradiction of the well-ordering property of \(\mathbb{N}\) is readily obtained.

\begin{observation}
If \(s \in C_N\) then \(s\) reduces to a unique numeral.
\end{observation}

**Proof.** Since \(C_N\) contains only \(CT\)-coterms, we have as a special case of Theorem 4.6 that \(s \equiv n\) for some \(n \in \mathbb{N}\). By confluence, we have that \(n\) is unique and furthermore \(s \prec n\).

Proof of Theorem 5.8. Suppose for contradiction we have \(\vec{s} \in C_\vec{f}\) such that \(\vec{t} \vec{s} \notin C_\vec{f}\). We define a branch \((t_i : \vec{f} \Rightarrow \tau)_i\) of \(t\) and inputs \(\vec{s}_i \in C_\vec{f}\) s.t. \(t_i, \vec{s}_i \notin C_\vec{f}\), by induction on \(i\) just like in Definition 4.2 (or the proof of Proposition 2.11). The only difference is that we use Proposition 5.7 above for preservation in \(\mathcal{C}\) rather than the analogous closure properties for \(\text{HR}\) (or \(\mathbb{N}\)).

There is one subtlety, which is the treatment of the \(\text{cond}\) case. Suppose we have a regular progressing codereivation,

\[
\begin{array}{c}
\text{cond} \ \
\hline
\vec{\tau} \Rightarrow \vec{t} \\
\vec{\sigma} \Rightarrow \tau \\
\end{array}
\]

and \(\vec{s}_i = (\vec{\sigma}, \vec{s})\) with \(\vec{s} \in C_\vec{f}\), \(s \in C_N\) and \(\text{cond} \ t' \vec{s} \notin C_\vec{f}\). Since \(s \in C_N\) we have from Observation B.1 that \(s\) reduces to a unique numeral \(n\). We will show that,
if \( n = 0 \) then \( \vec{s} \notin C_T \); and,
if \( n = m + 1 \) then there is some \( r \in C_N \) reducing to \( m \) with \( t' \vec{s}r \notin C_T \);

by induction on \( \text{RedTree}(\vec{s}) + \text{RedTree}(s) \). By the conversion lemma, Lemma 5.6, there must be a reduction from \( \text{cond} t' \vec{s}s \) not reaching \( C_T \). Let us consider the possible cases:

- If \( s = 0 \) and \( \text{cond} t' \vec{s}s \leadsto t \vec{s} \notin C_T \) then we are done.
- If \( s = sr \) and \( \text{cond} t' \vec{s}s \leadsto t' \vec{s}r \notin C_T \) then we are done. (Note that such \( r \) must strongly normalise to \( m \), and so in particular \( r \in C_N \)).
- If \( \text{cond} t' \vec{s}s \leadsto \text{cond} t' \vec{s}'s' \notin C_T \), then by the inductive hypothesis either,
  - \( n = 0 \) and \( t \vec{s}' \notin C_T \), so \( t \vec{s} \notin C_T \) by Proposition 5.5.(2); or,
  - \( n = m + 1 \) and there is some \( r \in C_N \) reducing to \( m \) s.t. \( t' \vec{s}'r \notin C_T \), so \( t' \vec{s}r \notin C_T \) by Proposition 5.5.(2).

From here, any progressing thread \((N')_{i \geq k}\) along \((t_i)\), yields a sequence of coterms \((r_i \in C_N)_{i \geq k}\) that, under normalisation, induces an infinitely often descending sequence of natural numbers, yielding the required contradiction.
