Abstract

SAT/SMT-solvers and model checkers automate formal verification of sequential programs. Formal reasoning about scalable concurrent programs is still manual and requires expert knowledge. But scalability is a fundamental requirement of current and future programs.

Sequential imperative programs compose statements, function/method calls and control flow constructs. Concurrent programming models provide constructs for concurrent composition. Concurrency abstractions such as threads and synchronization primitives such as locks compose the individual parts of a concurrent program that are meant to execute in parallel. We propose to rather compose the individual parts again using sequential composition and compile this sequential composition into a concurrent one. The developer can use existing tools to formally verify the sequential program while the translated concurrent program provides the dearly requested scalability.

Following this insight, we present ConDRust, a new programming model and compiler for Rust programs. The ConDRust compiler translates sequential composition into a concurrent composition based on threads and message-passing channels. During compilation, the compiler preserves the semantics of the sequential program along with much desired properties such as determinism.

Our evaluation shows that our ConDRust compiler generates concurrent deterministic code that can outperform even non-deterministic programs by up to a factor of three for irregular algorithms that are particularly hard to parallelize.
1 Scope

This artifact aims to back the performance claims made in the accompanying paper. It contains our presented implementations of various benchmarks from the STAMP [3], PARSEC [1] and YCSB [2] suites. We also include the build of the ConDRust compiler (named ohuac) used to generate the code for the benchmarks as well as all external libraries used.

Additionally, this repository contains the proof that an explicit panic we inserted in the code as part of our optimization is never encountered in the sequential version of the code.

2 Content

The artifact package is a Docker image which includes:
- The ConDRust compiler, named ohuac (binary)
- A patched version of the rust-stm library fixing a deadlock problem (code)
  Original available on https://github.com/Marthog/rust-stm.
- A library providing rudimentary STM-aware data structures (code)
- Performance benchmarks for various benchmarks from STAMP and PARSEC that appeared in our paper (benchmark)
- A Key-Value Store implementation also appearing in our paper (benchmark)
- A correctness proof for the absence of panics in an optimization we perform (proof)

3 Getting the artifact

The artifact endorsed by the Artifact Evaluation Committee is available free of charge on the Dagstuhl Research Online Publication Server (DROPS).

4 Tested platforms

The artifact is provided as Docker file and should therefore run on all platforms supported by the software. It is known to run on Ubuntu 22.04, NixOS 22.11 and macOS 13.

5 License

The artifact is available under Creative Commons Attribution 4.0 International license (CC BY 4.0).
