

Stream Processors and Comodels

Richard Garner   

Department of Mathematics and Statistics, Macquarie University, Sydney, Australia

Abstract

In 2009, Ghani, Hancock and Pattinson gave a coalgebraic characterisation of stream processors $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ drawing on ideas of Brouwerian constructivism. Their stream processors have an *intensional* character; in this paper, we give a corresponding coalgebraic characterisation of *extensional* stream processors, i.e., the set of continuous functions $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$. Our account sites both our result and that of *op. cit.* within the apparatus of *comodels* for algebraic effects originating with Power–Shkaravska.

1 Introduction

As is well known, the type of infinite *streams* of elements of some type A may be defined to be the final coalgebra $\nu X. A \times X$. If types are mere sets, then this coalgebra is manifested as the set $A^{\mathbb{N}}$ of infinite lists of A -elements, with the structure map

$$\alpha: \vec{a} \mapsto (a_0, \partial \vec{a}) \quad \text{where} \quad \partial(a_0, a_1, a_2, \dots) = (a_1, a_2, \dots). \quad (1)$$

Of course, the coalgebra structure describes the corecursive nature of streams, but also captures their sequentiality: an A -stream is *first* an A -value, and *then* an A -stream.

If A and B are types, then an A - B -stream processor is a way of turning an A -stream into a B -stream. If types are sets, then the crudest kind of stream processor would simply be a function $f: A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$; however, it is more computationally reasonable to restrict to those f which are *productive*, in the sense that determining each B -token of the output should require examining only a finite number of A -tokens of the input.

The productive functions $f: A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ are in fact precisely the *continuous* ones for the prodiscrete (= Baire) topologies on $A^{\mathbb{N}}$ and $B^{\mathbb{N}}$. While this representation of stream processors is mathematically smooth, it fails to make explicit their sequentiality: we should like to see the fact that determining each *successive* token of the output B -stream requires examining *successive* finite segments of the input A -stream. Much as for streams themselves, this can be done by presenting stream processors as a final coalgebra.

Such a presentation was given in [7]. Therein, the *type of A - B -stream processors* was taken to be the final coalgebra $\nu X. T_A(B \times X)$, where $T_A(V) = \mu X. V + X^A$; and it was explained how each element of this type encodes a continuous function $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$, and how, conversely, each such continuous function yields an element of this type. An interesting aspect of the story is that these assignments are *not* mutually inverse: distinct elements of $\nu X. T_A(B \times X)$ may represent the same continuous function, so that elements of this type are really *intensional* representations of stream-processing algorithms.

While there are many perspectives from which this is a good thing, it leaves open the question of whether there is a coalgebraic representation for *extensional* stream processors, i.e., for the bare set of continuous functions $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$. In this paper, we show that there is:

► **Theorem 1.** *Let A and B be sets. The set of continuous functions $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ is the underlying set of the terminal B -ary comagma in the category of A -ary magmas.*

In this result, an A -ary magma is a set X with an operation $\xi: X^A \rightarrow X$ satisfying no further axioms. More generally, we can speak of A -ary magmas in any category \mathcal{C} with products; while, if \mathcal{C} is a category with coproducts, we can define an A -ary comagma in \mathcal{C} to be an A -ary magma in \mathcal{C}^{op} . Explicitly, this involves an object $X \in \mathcal{C}$ and a map $X \rightarrow X + \cdots + X$ into the coproduct of A copies of X , subject to no further conditions.

On the face of it, our Theorem 1 has no obvious relation to [7], nor to anything resembling computation. Thus, the broader contribution of this paper is to site both the ideas of [7] and our Theorem 1 within the well-established machinery of *comodels* [21, 20], as we now explain.

The category-theoretic approach to computational effects originates in [16]: given a monad \mathbb{T} on a category of types and programs, we view elements of $T(V)$ as computations with side-effects from \mathbb{T} returning values in V . This idea was refined in [19]; rather than considering monads *simpliciter*, we generate them from *algebraic theories* whose basic operations are the computational primitives for the effects at issue. A key example, for us, is the theory \mathbb{T}_A of input from an alphabet A , which is freely generated by a single A -ary operation *read*.

The approach via algebraic theories has the virtue of giving a good notion of *model* in any category with finite powers. In particular, one has *comodels*, which are models in the opposite of the category of sets, and a key insight of [21] is that comodels of a theory \mathbb{T} can be seen as coalgebraic objects for evaluating \mathbb{T} -computations to values: for example, a \mathbb{T}_A -comodel is an $A \times (-)$ -coalgebra, and the *final* comodel is the set of A -streams.

A range of authors [20, 15, 17, 18, 23, 10, 1, 6, 24, 5] have taken this attractive perspective on operational semantics further. Particularly salient for us is the concept, due to [1, 10, 24] of a *residual comodel*. Given theories \mathbb{T} and \mathbb{R} , an \mathbb{R} -residual \mathbb{T} -comodel is, formally speaking, a comodel of \mathbb{T} in the Kleisli category of \mathbb{R} but is, practically speaking, a coalgebraic entity for evaluating or compiling \mathbb{T} -computations into \mathbb{R} -computations. In particular, we have \mathbb{T}_A -residual \mathbb{T}_B -comodels, which translate requests for B -input into requests for A -input, and a little thought shows that this is exactly the rôle filled by an A - B -stream processor. In fact, the final coalgebra of [7] turns out to be precisely the *final* \mathbb{T}_A -residual \mathbb{T}_B -comodel; in §3 we explain this, and show how other aspects of [7] flow naturally from this fact.

To get from here to our Theorem 1 requires a new import from category-theoretic universal algebra: the notion of a *bimodel* [4, 22, 3]. An \mathbb{R} - \mathbb{T} -bimodel is a comodel of \mathbb{T} in the category of *Set*-models of \mathbb{R} . Since this latter category has the Kleisli category as a full subcategory, bimodels are a generalisation of residual comodels – one which, roughly speaking, allows additional quotients by bisimulations to be taken. These quotients are just what one needs to collapse the intensional stream processors of [7] to their underlying continuous functions: so yielding our Theorem 1 which we now recognise as describing the *final* \mathbb{T}_A - \mathbb{T}_B -bimodel.

There is plenty more to be said in this direction: our results map a path toward studying residual comodels and bimodels of other theories, with notions like hidden Markov models, or non-deterministic and Rabin automata, all within scope. But this must await another paper!

2 Streams as a final comodel

In this background section, we recall how algebraic theories present notions of effectful computation, how *comodels* of a theory furnish environments appropriate for evaluating such computations, and how the type of streams arises as a final comodel.

► **Definition 2** (Algebraic theory). A signature comprises a set Σ of function symbols, and for each $\sigma \in \Sigma$ a set $|\sigma|$, its arity. Given a signature Σ and a set V , we define the set $\Sigma(V)$ of Σ -terms with variables in V by the inductive clauses

$$v \in V \implies v \in \Sigma(V) \quad \text{and} \quad \sigma \in \Sigma, t \in \Sigma(V)^{|\sigma|} \implies \sigma(t) \in \Sigma(V) .$$

An equation over a signature Σ is a formal equality $t = u$ between terms in the same set of free variables. A (algebraic) theory \mathbb{T} comprises a signature and a set of equations over it.

► **Definition 3** (\mathbb{T} -terms). Given a signature Σ and terms $t \in \Sigma(V)$ and $u \in \Sigma(W)^V$, we define the substitution $t(u) \in \Sigma(W)$ by recursion on t :

$$v \in V \implies v(u) = u_v \quad \text{and} \quad \sigma \in \Sigma, t \in \Sigma(V)^{|\sigma|} \implies (\sigma(t))(u) = \sigma(\lambda i. t_i(u)) .$$

Given a theory \mathbb{T} with signature Σ , we define \mathbb{T} -equivalence as the smallest family of substitution-congruences $\equiv_{\mathbb{T}}$ on the sets $\Sigma(V)$ such that $t \equiv_{\mathbb{T}} u$ for all equations $t = u$ of \mathbb{T} . The set $T(V)$ of \mathbb{T} -terms with variables in V is $\Sigma(V)/\equiv_{\mathbb{T}}$.

When a theory \mathbb{T} is seen as specifying a computational effect, $T(V)$ describes the set of computations with effects from \mathbb{T} returning a value in V . There are theories for effects such as output, state, exceptions, and so on, but for us the salient example is:

► **Example 4** (Input). Given a set A , the theory \mathbb{T}_A of A -valued input comprises a single A -ary function symbol `read`, satisfying no equations, whose action we think of as:

$$(t : A \rightarrow X) \mapsto \text{let read() be } a. t(a) .$$

The set of terms $T_A(V)$ is, as in the introduction, the initial algebra $\mu X. V + X^A$, whose elements may be seen combinatorially as A -ary branching trees with leaves labelled in V ; or computationally as programs which request A -values from an external source and use them to determine a return value in V . For example, when $A = \mathbb{N}$, the program which requests two input values and returns their sum is presented by

$$\text{let read() be } n. \text{let read() be } m. n + m \in T(\mathbb{N}) . \tag{2}$$

We now define the models of an algebraic theory. In the definition, we say that a category \mathcal{C} has *powers* if it has all set-indexed self-products $X^A := \prod_{a \in A} X$.

► **Definition 5** (Σ -structure, \mathbb{T} -model). Let Σ be a signature. A Σ -structure \mathbf{X} in a category \mathcal{C} with powers is an object $X \in \mathcal{C}$ with operations $\llbracket \sigma \rrbracket_{\mathbf{X}} : X^{|\sigma|} \rightarrow X$ for each $\sigma \in \Sigma$. For each $t \in \Sigma(V)$ the derived operation $\llbracket t \rrbracket_{\mathbf{X}} : X^V \rightarrow X$ is then determined by the recursive clauses:

$$\llbracket v \rrbracket_{\mathbf{X}} = \pi_v \quad \text{and} \quad \llbracket \sigma(t) \rrbracket_{\mathbf{X}} = X^V \xrightarrow{(\llbracket t_i \rrbracket_{\mathbf{X}})_{i \in |\sigma|}} X^{|\sigma|} \xrightarrow{\llbracket \sigma \rrbracket_{\mathbf{X}}} X . \tag{3}$$

Given a theory $\mathbb{T} = (\Sigma, \mathcal{E})$, a \mathbb{T} -model in \mathcal{C} is a Σ -structure \mathbf{X} which satisfies $\llbracket t \rrbracket_{\mathbf{X}} = \llbracket u \rrbracket_{\mathbf{X}}$ for all equations $t = u$ of \mathbb{T} . The unqualified term “model” will always mean “model in *Set*”. We write $\text{Mod}(\mathbb{T}, \mathcal{C})$ for the category of \mathbb{T} -models in \mathcal{C} , and $\text{Mod}(\mathbb{T})$ for the models in *Set*.

The set of computations $T(V)$ has a structure of \mathbb{T} -model $\mathbf{T}(V)$ with operations given by substitution; and as is well known, this structure is in fact *free*:

► **Lemma 6.** The inclusion of variables $\eta_V : V \rightarrow T(V)$ exhibits $\mathbf{T}(V)$ as the free \mathbb{T} -model on V . That is, for any \mathbb{T} -model \mathbf{X} and any function $f : V \rightarrow X$, there is a unique \mathbb{T} -model homomorphism $f^\dagger : \mathbf{T}(V) \rightarrow \mathbf{X}$ with $f^\dagger \circ \eta_V = f$. Explicitly, $f^\dagger(t) = \llbracket t \rrbracket_{\mathbf{X}}(\lambda v. f(v))$.

15:4 Stream Processors and Comodels

Taking the full subcategory of $Mod(\mathbb{T})$ on the free \mathbb{T} -models yields the well known *Kleisli category* of \mathbb{T} , which we typically present as follows:

► **Definition 7** (Kleisli category). *The Kleisli category $Kl(\mathbb{T})$ of a theory \mathbb{T} has sets as objects; hom-sets $Kl(\mathbb{T})(A, B) = Set(A, TB)$; the identity at A being $\eta_A: A \rightarrow TA$; and composition $g, f \mapsto g^\dagger \circ f$ with g^\dagger as in Lemma 6 for the free \mathbb{T} -model structures. The free functor $F_{\mathbb{T}}: Set \rightarrow Kl(\mathbb{T})$ is the identity on objects and sends $f \in Set(X, Y)$ to $\eta_Y \circ f \in Kl(\mathbb{T})(X, Y)$. The fully faithful comparison functor $I_{\mathbb{T}}: Kl(\mathbb{T}) \rightarrow Mod(\mathbb{T})$ maps $A \mapsto \mathbf{T}A$ and $f \mapsto f^\dagger$.*

The Kleisli category captures the compositionality of computations with effects from \mathbb{T} , and allows us to draw the link with Moggi's monadic semantics [16]; indeed, the free functor $F_{\mathbb{T}}: Set \rightarrow Kl(\mathbb{T})$ and its right adjoint $Kl(\mathbb{T})(1, -): Kl(\mathbb{T}) \rightarrow Set$ generate an associated monad \mathbf{T} on Set and we have that $Kl(\mathbb{T}) \cong Kl(\mathbf{T})$ under Set .

So far we have said nothing about *non-free* \mathbb{T} -models. It is a basic fact that every such model can be obtained from a free one by quotienting by some congruence, and so can be seen as a set of computations identified up to some notion of program equivalence. This is important, for example, in [12], and will be important for us in §4 below.

We now turn from models to the dual notion of *comodel*. We say a category \mathcal{C} has *copowers* if if each set-indexed self-coproduct $A \cdot X = \Sigma_{a \in A} X$ exists in \mathcal{C} .

► **Definition 8** (\mathbb{T} -comodel). *Let \mathbb{T} be a theory. A \mathbb{T} -comodel in a category \mathcal{C} with copowers is a model of \mathbb{T} in \mathcal{C}^{op} , comprising an object $S \in \mathcal{C}$ and co-operations $\llbracket \sigma \rrbracket^S: S \rightarrow |\sigma| \cdot S$ obeying the equations of \mathbb{T} . The unqualified term “comodel” will mean “comodel in Set ”. We write $Comod(\mathbb{T}, \mathcal{C})$ for the category of \mathbb{T} -comodels in \mathcal{C} , and $Comod(\mathbb{T})$ for the comodels in Set .*

As explained in [21, 20], when a theory \mathbb{T} presents a notion of computation, its comodels provide deterministic environments for evaluating computations with effects from \mathbb{T} .

► **Example 9.** A comodel \mathbf{S} of the theory of A -valued input is a state machine that answers requests for A -characters; it comprises a set of states S and a map $\llbracket read \rrbracket^{\mathbf{S}} = (g, n): S \rightarrow A \times S$ giving for each $s \in S$ a next character $g(s) \in A$ and a next state $n(s) \in S$.

While the comodels of the preceding example are just $A \times (-)$ -coalgebras, the comodel perspective adds something to this. The general picture is that a \mathbb{T} -comodel allows us to evaluate \mathbb{T} -computations $t \in T(V)$ down to values in V via the derived operations of Definition 5. Indeed, given a comodel \mathbf{S} and a term $t \in T(V)$, we have the derived co-operation $\llbracket t \rrbracket^{\mathbf{S}}: S \rightarrow V \times S$ which, unfolding the definition, is given by the clauses:

$$\begin{aligned} v \in V &\implies \llbracket v \rrbracket^{\mathbf{S}}(s) = (v, s) \\ \text{and } \sigma \in \Sigma, t \in T(V)^{|\sigma|} &\implies \llbracket \sigma(t) \rrbracket^{\mathbf{S}}(s) = \llbracket t_v \rrbracket^{\mathbf{S}}(s') \text{ where } \llbracket \sigma \rrbracket^{\mathbf{S}}(s) = (v, s'). \end{aligned} \quad (4)$$

The idea is that applying $\llbracket t \rrbracket^{\mathbf{S}}$ to a starting state $s \in S$ will yield the value $v \in V$ and final state $s' \in S$ obtained by running the computation $t \in T(V)$, using the co-operations of the comodel \mathbf{S} to answer the requests posed by the corresponding operation symbols of \mathbb{T} .

► **Example 10.** For a comodel $(g, n): S \rightarrow A \times S$ of A -valued input, the clauses (4) become

$$v \in V \implies \llbracket v \rrbracket^{\mathbf{S}}(s) = (v, s) \quad t \in T(V)^A \implies \llbracket read(t) \rrbracket^{\mathbf{S}}(s) = \llbracket t(g(s)) \rrbracket^{\mathbf{S}}(n(s)).$$

So if we consider $A = \mathbb{N}$, the term $t = read(\lambda n. read(\lambda m. n + m)) \in T(\mathbb{N})$ from (2), and the comodel \mathbf{S} with $S = \{s, s', s''\}$ and $\llbracket read \rrbracket^{\mathbf{S}} = (g, n): S \rightarrow \mathbb{N} \times S$ given by the upper line in:

$$\begin{aligned} \llbracket read \rrbracket^{\mathbf{S}}: & \quad s \mapsto (3, s') & \quad s' \mapsto (6, s'') & \quad s'' \mapsto (11, s'') \\ \llbracket t \rrbracket^{\mathbf{S}}: & \quad s \mapsto (9, s'') & \quad s' \mapsto (17, s'') & \quad s'' \mapsto (22, s'') , \end{aligned}$$

then $\llbracket t \rrbracket^S : S \rightarrow \mathbb{N} \times S$ is given by the lower line. For example, we calculate that $\llbracket t \rrbracket(s) = \llbracket \text{read}(\lambda n. \text{read}(\lambda m. n + m)) \rrbracket(s) = \llbracket \text{read}(\lambda m. 3 + m) \rrbracket(s') = \llbracket 3 + 6 \rrbracket(s'') = (9, s'')$.

As is idiomatic, the *final* comodel of a theory describes “observable behaviours” that states of a comodel may possess. To make this precise, we define states $s_1 \in \mathbf{S}_1$ and $s_2 \in \mathbf{S}_2$ of two \mathbb{T} -comodels to be *operationally equivalent* if running any \mathbb{T} -computation $t \in T(V)$ starting from the state s_1 of \mathbf{S}_1 or from the state s_2 of \mathbf{S}_2 gives the same value; i.e.,

$$\text{if } \llbracket t \rrbracket^{\mathbf{S}_1}(s_1) = (v_1, s'_1) \quad \text{and} \quad \llbracket t \rrbracket^{\mathbf{S}_2}(s_2) = (v_2, s'_2) \quad \text{then} \quad v_1 = v_2 .$$

► **Lemma 11.** *States $s_1 \in \mathbf{S}_1$ and $s_2 \in \mathbf{S}_2$ of two \mathbb{T} -comodels are operationally equivalent if and only if they become equal under the unique maps $\mathbf{S}_1 \rightarrow \mathbf{F} \leftarrow \mathbf{S}_2$ to the final \mathbb{T} -comodel.*

Proof. This is [5, Proposition 52]. ◀

So in the spirit of [11, Theorem 4], we may (if we adequately handle the set-theoretic issues) characterise the final \mathbb{T} -comodel as the set of all possible states of all possible comodels, modulo operational equivalence. For A -valued input, two states s_1, s_2 of two comodels $(g_i, n_i) : S_i \rightarrow A \times S_i$ are operationally equivalent if they give the same stream of values:

$$(g_1(s_1), g_1(n_1(s_1)), g_1(n_1(n_1(s_1))), \dots) = (g_2(s_2), g_2(n_2(s_2)), g_2(n_2(n_2(s_2))), \dots) ,$$

and in this way, we may reconstruct the familiar fact that the final \mathbb{T}_A -comodel $\mathbf{A}^{\mathbb{N}}$ is the set of A -streams $A^{\mathbb{N}}$ with the structure map (1).

The comodel view also allows us to capture the *topology* on the space of streams. Indeed, any comodel of a theory has a natural prodiscrete topology, whose basic open sets describe those states which are indistinguishable with respect to a finite set of \mathbb{T} -computations.

► **Definition 12** (Operational topology). *Let \mathbf{S} be a \mathbb{T} -comodel. The operational topology on \mathbf{S} is generated by sub-basic open sets*

$$[t \mapsto v] := \{s \in S : \llbracket t \rrbracket^S(s) = (v, s') \text{ for some } s'\} \quad \text{for all } t \in T(V) \text{ and } v \in V .$$

This definition appears to be new, and investigating its force is beyond the scope of this paper; in particular, we have space only to state the following result, whose proof the reader may find an interesting exercise. It implies easily that $\mathbf{A}^{\mathbb{N}}$ is the final *topological* comodel when given the topology obtained from the product of discrete topologies on each copy of A .

► **Lemma 13.** *For any theory \mathbb{T} , the final \mathbb{T} -comodel \mathbf{F} , when endowed with its operational topology, is the final topological comodel.*

3 Intensional stream processors as a final residual comodel

In this section, we recall a more general kind of comodel considered by, among others, [1, 10, 24], which allows for stateful translations between different notions of computation. We then explain how the intensional stream processors of [7] instantiate this notion, and use this fact to derive a number of other aspects of the theory of [7].

► **Definition 14** (Residual comodel). *Let \mathbb{T} and \mathbb{R} be theories. An \mathbb{R} -residual \mathbb{T} -comodel is a comodel of \mathbb{T} in the Kleisli category $Kl(\mathbb{R})$.*

The nomenclature “residual” comes from [10, §5.3], and we will explain the connection to *loc. cit.* in Proposition 25 below. For now, let us spell out in detail what a residual comodel \mathbf{S} involves. First, there is an underlying set of states S . Next, we have for each $\sigma \in \Sigma$ a basic co-operation $\llbracket \sigma \rrbracket^{\mathbf{S}} : S \rightarrow R(|\sigma| \times S)$ assigning to each state $s \in S$ an \mathbb{R} -computation $\llbracket \sigma \rrbracket^{\mathbf{S}}(s)$ returning values in $|\sigma| \times S$ – where, as before, we think of these two components as providing a value answering the request posed by σ , and a next state. Now we determine a derived co-interpretation $\llbracket t \rrbracket^{\mathbf{S}} : S \rightarrow R(V \times S)$ for each $t \in T(V)$ by threading the basic co-operations together via monadic binding:

$$\begin{aligned} v \in V \subseteq T(V) &\implies \llbracket v \rrbracket^{\mathbf{S}}(s) = (v, s) \in V \times S \subseteq R(V \times S) \\ \text{and } \sigma \in \Sigma, t \in T(V)^{|\sigma|} &\implies \llbracket \sigma(t) \rrbracket^{\mathbf{S}}(s) = \llbracket \sigma \rrbracket^{\mathbf{S}}(s)(\lambda(v, s'). \llbracket t_v \rrbracket^{\mathbf{S}}(s')) , \end{aligned} \quad (5)$$

and the final requirement is that these derived operations should satisfy the equations of \mathbb{T} .

Interesting examples of residual comodels are given in [1, 24, 9], but for us the key case is:

► **Example 15.** A comodel of the theory \mathbb{T}_B of B -valued input residual on the theory \mathbb{T}_A of A -valued input comprises a set of states S , and a function $\gamma : S \rightarrow T_A(B \times S)$ assigning to each state $s \in S$ a program which uses some number of A -tokens from an input stream to inform the choice of an output B -token and a new state in S .

It is easy to see how each state s_0 of such a comodel should encode a stream processor $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$: given an input stream $\vec{a} \in A^{\mathbb{N}}$, we consume some initial segment a_0, \dots, a_k to answer the requests posed by the program $\gamma(s_0)$, so obtaining an element $b_0 \in B$ and a new state s_1 . We now repeat starting from $s_1 \in S$ and the remaining part $\partial^k \vec{a}$ of the input stream, to obtain b_1 and s_2 while consuming a_{k+1}, \dots, a_ℓ ; and so on coinductively. This description was made mathematically precise in [7, §3.1], but in fact we can obtain it in a principled comodel-theoretic manner via (a special case of) a notion given in [20, Appendix].

► **Definition 16** (Tensor of a residual comodel with a comodel). *Let \mathbb{T} and \mathbb{R} be theories. Let \mathbf{S} be an \mathbb{R} -residual \mathbb{T} -comodel, and let \mathbf{M} be an \mathbb{R} -comodel. The tensor product $\mathbf{S} \cdot \mathbf{M}$ is the \mathbb{T} -comodel with underlying set $S \times M$ and co-operations*

$$\llbracket \sigma \rrbracket^{\mathbf{S} \cdot \mathbf{M}} : S \times M \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{S}} \times M} R(|\sigma| \times S) \times M \xrightarrow{(t, m) \mapsto \llbracket t \rrbracket^{\mathbf{M}}(m)} |\sigma| \times S \times M . \quad (6)$$

This definition makes intuitive sense: given a state machine for translating \mathbb{T} -computations into \mathbb{R} -computations, and one for executing \mathbb{R} -computations, it threads them together to yield a state machine for executing \mathbb{T} -computations. We will make this justification rigorous in Definition 26 below, but for the moment let us simply assume its reasonability and give:

► **Definition 17** (Extent). *The extent of a \mathbb{T}_A -residual \mathbb{T}_B -comodel \mathbf{S} is the function $e : S \times A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ underlying the unique map of \mathbb{T}_B -comodels $\mathbf{S} \cdot \mathbf{A}^{\mathbb{N}} \rightarrow \mathbf{B}^{\mathbb{N}}$, where here $\mathbf{A}^{\mathbb{N}}$ and $\mathbf{B}^{\mathbb{N}}$ are endowed with their final comodel structures.*

We now unfold this definition. Firstly, for any term $t \in T_A(V)$, the derived co-operation $\llbracket t \rrbracket^{\mathbf{A}^{\mathbb{N}}}(\vec{a}) : A^{\mathbb{N}} \rightarrow V \times A^{\mathbb{N}}$ is defined recursively by

$$\llbracket v \rrbracket^{\mathbf{A}^{\mathbb{N}}}(\vec{a}) = (v, \vec{a}) \quad \text{and} \quad \llbracket \text{read}(t) \rrbracket^{\mathbf{A}^{\mathbb{N}}}(\vec{a}) = \llbracket t(a_0) \rrbracket(\partial \vec{a}) . \quad (7)$$

If we view t as an A -ary branching tree with leaves labelled in V , then $\llbracket t \rrbracket^{\mathbf{A}^{\mathbb{N}}}(\vec{a})$ is the result of walking up the tree from the root, consuming an element of \vec{a} at each interior node to

determine which branch to take, and returning at a leaf the V -value found there along with what remains of \vec{a} . Now, in terms of this, the \mathbb{T}_B -comodel structure of $\mathbf{S} \cdot \mathbf{A}^{\mathbb{N}}$ is given by

$$S \times A^{\mathbb{N}} \rightarrow B \times S \times A^{\mathbb{N}} \quad (s, \vec{a}) \mapsto [\gamma(s)]^{\mathbf{A}^{\mathbb{N}}}(\vec{a}) ;$$

that is, by the function taking a state s_0 and stream \vec{a} to the triple $(b_0, s_1, \partial^k \vec{a})$ obtained by walking up k nodes of the tree $\gamma(s_0)$ to the leaf (b_0, s_1) . If we view this comodel structure as a pair of maps $g: S \times A^{\mathbb{N}} \rightarrow B$ and $n: S \times A^{\mathbb{N}} \rightarrow S \times A^{\mathbb{N}}$, then we can say, finally, that the extent function $e: S \times A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ of \mathbf{S} is defined coinductively by:

$$(e(s, \vec{a}))_0 = g(s, \vec{a}) \quad \partial(e(s, \vec{a})) = e(n(s, \vec{a})) .$$

Comparing this construction with that of [7, §3.1], done there with bare hands, we find that they are exactly the same: the derived co-operations $[[t]]$ of (7) are the functions $eat\ t$ of *loc. cit.*, while our extent function e is their function eat_{∞} .

We have thus shown that each state s of a \mathbb{T}_A -residual \mathbb{T}_B -comodel encodes a function $e(s, -): A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$; but for these functions to be reasonable stream processors, they should be *continuous* for the profinite topologies. While this may be shown with little effort, we may in fact see it without *any* effort via a comodel-theoretic argument. We first need:

► **Definition 18** (Tensor of a residual comodel and a topological comodel). *Let \mathbb{T} and \mathbb{R} be theories, let \mathbf{S} be an \mathbb{R} -residual \mathbb{T} -comodel, and \mathbf{M} a topological \mathbb{R} -comodel. The tensor product $\mathbf{S} \cdot \mathbf{M}$ is the topological \mathbb{T} -comodel with underlying space $S \cdot M$ and co-operations (6).*

Once again, the justification for this definition will be given below; assuming it for now, the desired continuity of each $e(s, -)$ is immediate. For indeed, viewing $\mathbf{A}^{\mathbb{N}}$ and $\mathbf{B}^{\mathbb{N}}$ as final topological comodels, there is a unique map of topological \mathbb{T}_B -comodels $\mathbf{S} \cdot \mathbf{A}^{\mathbb{N}} \rightarrow \mathbf{B}^{\mathbb{N}}$ which, since forgetting the topology yields back a map of *Set*-comodels, must be the extent function e . Thus, the force of this is that e is continuous as a map $S \cdot A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ – which is equally to say that each $e(s, -): A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ is continuous for the profinite topologies.

So far, our argument has been given for an arbitrary \mathbb{T}_A -residual \mathbb{T}_B -comodel \mathbf{S} ; but as in [7], it is natural to consider the final residual comodel in particular. To this end, we should first clarify the correct notion of *morphism* between residual comodels.

► **Definition 19** (Map of residual comodels). *Let \mathbb{T} and \mathbb{R} be theories, and let \mathbf{S} and \mathbf{U} be \mathbb{R} -residual \mathbb{T} -comodels. A map of residual comodels $\mathbf{S} \rightarrow \mathbf{U}$ is a function $f: S \rightarrow U$ such that $[[\sigma]]^{\mathbf{U}} \circ f = R(|\sigma| \times f) \circ [[\sigma]]^{\mathbf{S}}$ for all operations σ in the signature of \mathbb{T} .*

► **Remark 20.** Given that an \mathbb{R} -residual comodel is a comodel in $Kl(\mathbb{R})$, we might expect a map of residual comodels to be a map in $Kl(\mathbb{R})$, rather than one in *Set*. The reason for our unusual choice is not pure expediency; it has to do with an enrichment of the category of theories in the category of comonads on *Set*, currently being investigated by the authors of [10], and which exploits the general *Sweedler theory* of [2]. Working through the calculations, one finds that for two theories \mathbb{R} and \mathbb{T} , the category of coalgebras for the hom-comonad $\langle \mathbb{R}, \mathbb{T} \rangle$ is the category of residual comodels, with precisely the maps indicated in Definition 19.

With this clarification made, we see that, in particular, the category of \mathbb{T}_A -residual \mathbb{T}_B -comodels is simply the category of $T_A(B \times -)$ -coalgebras, and so we have:

► **Definition 21** (Intensional stream processors). *The type of intensional A - B -stream processors is the final \mathbb{T}_A -residual \mathbb{T}_B -comodel \mathbf{I}_{AB} , i.e., the final coalgebra $\nu X. T_A(B \times X)$. The reflection function is the currying of the topological extent function*

$$\text{reflect}: I_{AB} \rightarrow \text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}}) \quad s \mapsto e(s, -): A^{\mathbb{N}} \rightarrow B^{\mathbb{N}} ,$$

where here we write *Top* for the category of topological spaces and continuous maps.

As well as reflection, [7] also defines a *reification* function $\text{reify}: \text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}}) \rightarrow I_{AB}$ that implements each continuous function by a state of the final comodel, and which satisfies $\text{reflect} \circ \text{reify} = \text{id}$. This means that reflect is surjective – but crucially, it is *not* injective. To show this, we must first note that, by the usual techniques, the terminal coalgebra I_{AB} may be described as follows: it is the set of all finite or infinite A -ary branching trees, with interior nodes labelled with elements of B^* (i.e., lists of elements of B), with leaves labelled by elements of $B^{\mathbb{N}}$, and where no infinite path of interior nodes is labelled by the empty list.

► **Example 22.** Fix an element $b \in B$ and consider the following two \mathbb{T}_A -residual \mathbb{T}_B -comodel structures on $\{*\}$:

$$(i) * \mapsto (b, *) \quad \text{and} \quad (ii) * \mapsto \text{read}(\lambda a. (b, *)) . \quad (8)$$

In both comodels, the unique state $*$ encodes the continuous function $A^{\mathbb{N}} \rightarrow B^{\mathbb{N}}$ sending every stream \vec{a} to (b, b, b, b, \dots) . However, these states yield different elements of the final comodel I_{AB} : (i) gives the trivial tree t_0 whose root is labelled by (b, b, b, \dots) , while (ii) gives the purely infinite A -ary branching tree t_1 with every node labelled by a single b .

Intuitively, the two states of I_{AB} in this example differ in that the first ignores its input stream entirely, and simply outputs b 's without cease; while the second frivolously consumes a single A -token before emitting each b . So I_{AB} is a set of *intensional* representations of stream processors. This leads us neatly on to the second part of the paper, where we give a comodel-theoretic presentation of *extensional* stream processors, i.e., the set $\text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}})$, and an explanation in these terms of where the reification function of [7] comes from.

Before doing this, we resolve some unfinished business by justifying Definitions 16 and 18 above. Our starting point will be an alternative presentation of the notion of comodel due to [23]. In *op. cit.*, Uustalu defines a *runner* for a theory \mathbb{T} , with set of states S , to be a monad morphism $\mathbb{T} \rightarrow \mathbb{T}_S$ from the associated monad of \mathbb{T} to the state monad $\mathbb{T}_S = (- \times S)^S$. The data for such a runner are functions $T(V) \rightarrow (V \times S)^S$ assigning to each $t \in T(V)$ a function $[[t]]^S : S \rightarrow V \times S$. Recognising these as also being the data of the derived co-operations of a \mathbb{T} -comodel structure on S , we should find the main result of [23] reasonable: that \mathbb{T} -comodels with underlying set S are in bijection with \mathbb{T} -runners with underlying set of states S .

While Uustalu's result is about comodels in *Set*, it generalises unproblematically. For any object S of a category \mathcal{C} with copowers, we have an adjunction $(-) \cdot S \dashv \mathcal{C}(S, -) : \mathcal{C} \rightarrow \text{Set}$ inducing a monad $\mathbb{T}_S = \mathcal{C}(S, (-) \cdot S)$ on *Set*; in [15] this is called the *linear-use state monad* associated to S . We now have the following natural extension of Uustalu's result.

► **Proposition 23** (cf. [15, Theorem 8.2]). *Let \mathbb{T} be an algebraic theory, \mathcal{C} a category with copowers, and $S \in \mathcal{C}$. The following are in bijective correspondence:*

1. \mathbb{T} -comodels \mathcal{S} in \mathcal{C} with underlying object S ;
2. \mathbb{T} -runners in \mathcal{C} , i.e., monad maps $[[-]]^S : \mathbb{T} \rightarrow \mathbb{T}_S$ into the linear-use state monad of S ;
3. Functorial extensions of $(-) \cdot S : \text{Set} \rightarrow \mathcal{C}$ along the free functor into the Kleisli category:

$$\begin{array}{ccc} \text{Set} & \xrightarrow{(-) \cdot S} & \mathcal{C} \\ F_{\mathbb{T}} \downarrow & \nearrow & \uparrow \\ & & \mathcal{C}(S, -) \\ & \nearrow & \uparrow \\ \text{Kl}(\mathbb{T}) & & \mathcal{C}(S, (-) \cdot S) \end{array} \quad (9)$$

► **Remark 24.** Abstractly, this proposition expresses the fact that $\text{Kl}(\mathbb{T})$ is the *free category with copowers containing a comodel of \mathbb{T}* ; this result is originally due to Linton [13].

Proof. As just said, the argument for (1) \Leftrightarrow (2) is *mutatis mutandis* that of [23, §3]. For (2) \Leftrightarrow (3), it is standard [14] that monad maps $\mathbb{T} \rightarrow \mathbb{T}_S$ correspond to extensions to the left in:

$$\begin{array}{ccc} \text{Set} & \xrightarrow{F^{\mathbb{T}_S}} & \text{Kl}(\mathbb{T}_S) \\ F^{\mathbb{T}} \downarrow & \nearrow & \\ \text{Kl}(\mathbb{T}) & & \end{array} \quad \begin{array}{ccc} \text{Set} & \xrightarrow{(-) \cdot S} & \mathcal{C}_S \\ F_{\mathbb{T}} \downarrow & \nearrow & \\ \text{Kl}(\mathbb{T}) & & \end{array} .$$

Now the Kleisli category $\text{Kl}(\mathbb{T}_S)$ of the linear-use state monad is isomorphic to the category \mathcal{C}_S whose objects are sets, and whose maps $A \rightarrow B$ are \mathcal{C} -maps $A \cdot S \rightarrow B \cdot S$, via an isomorphism which identifies $F^{\mathbb{T}_S}$ with $(-) \cdot S : \text{Set} \rightarrow \mathcal{C}_S$. Similarly we have $\text{Kl}(\mathbb{T}) \cong \text{Kl}(\mathbb{T})$ under Set . So monad morphisms $\mathbb{T} \rightarrow \mathbb{T}_S$ correspond to extensions as right above: and these, by direct inspection, correspond to extensions as in (9). \blacktriangleleft

If here \mathcal{C} is itself the Kleisli category $\text{Kl}(\mathbb{R})$ of a theory \mathbb{R} , then the linear-use state monad of $S \in \text{Kl}(\mathbb{R})$ is the monad $\mathbb{R}(- \times S)^S$ found as the commuting combination of the state monad for S with the monad \mathbb{R} induced by \mathbb{R} (cf. [8, Theorem 10]). Monad maps $\mathbb{T} \rightarrow \mathbb{R}(S \times -)^S$ were in [10] termed \mathbb{R} -residual \mathbb{T} -runners, and for these the preceding result specialises to:

► **Proposition 25.** *Let \mathbb{T} and \mathbb{R} be algebraic theories and let S be a set. The following are in bijective correspondence:*

1. \mathbb{R} -residual \mathbb{T} -comodels \mathcal{S} with underlying set S ;
2. \mathbb{R} -residual \mathbb{T} -runners $\llbracket - \rrbracket^{\mathcal{S}} : \mathbb{T} \rightarrow \mathbb{R}(- \times S)^S$;
3. Functorial extensions of $(-) \times S : \text{Set} \rightarrow \text{Set}$ through the Kleisli categories of \mathbb{T} and \mathbb{R} :

$$\begin{array}{ccc} \text{Set} & \xrightarrow{(-) \times S} & \text{Set} \\ F_{\mathbb{T}} \downarrow & & \downarrow F_{\mathbb{R}} \\ \text{Kl}(\mathbb{T}) & \xrightarrow{(-) \cdot \mathcal{S}} & \text{Kl}(\mathbb{R}) \end{array} . \quad (10)$$

By putting together Propositions 23 and 25, we have an intuitive definition of *tensor product* for a residual comodel and a comodel, or for two residual comodels.

► **Definition 26** (Tensor product of residual comodels). *Let \mathbb{V} , \mathbb{T} , \mathbb{R} be theories; \mathcal{M} an \mathbb{R} -comodel in \mathcal{C} ; \mathcal{S} an \mathbb{R} -residual \mathbb{T} -comodel; and \mathcal{U} a \mathbb{T} -residual \mathbb{V} -comodel. The tensor product $\mathcal{S} \cdot \mathcal{M}$ is the \mathbb{T} -comodel in \mathcal{C} classified by the composite of extensions to the left below, while the tensor product $\mathcal{U} \cdot \mathcal{S}$ is the \mathbb{R} -residual \mathbb{V} -comodel classified by the composite to the right:*

$$\begin{array}{ccc} \text{Set} & \xrightarrow{(-) \times S} & \text{Set} & \xrightarrow{(-) \cdot \mathcal{M}} & \mathcal{C} \\ F_{\mathbb{T}} \downarrow & & \downarrow F_{\mathbb{R}} & \nearrow & \\ \text{Kl}(\mathbb{T}) & \xrightarrow{(-) \cdot \mathcal{S}} & \text{Kl}(\mathbb{R}) & & \end{array} \quad \begin{array}{ccc} \text{Set} & \xrightarrow{(-) \times \mathcal{U}} & \text{Set} & \xrightarrow{(-) \times S} & \text{Set} \\ F_{\mathbb{V}} \downarrow & & \downarrow F_{\mathbb{T}} & & \downarrow F_{\mathbb{R}} \\ \text{Kl}(\mathbb{V}) & \xrightarrow{(-) \cdot \mathcal{U}} & \text{Kl}(\mathbb{T}) & \xrightarrow{(-) \cdot \mathcal{S}} & \text{Kl}(\mathbb{R}) \end{array} . \quad (11)$$

In particular, when $\mathcal{C} = \text{Set}$ and $\mathcal{C} = \text{Top}$, the tensor product $\mathcal{S} \cdot \mathcal{M}$ just defined specialises to the tensor products of Definitions 16 and 18 above.

► **Remark 27.** Here is another perspective on Definition 26. To the left of (11), the functor $(-) \cdot \mathcal{M}$ preserves copowers, and so lifts to a functor $\text{Comod}(\mathbb{T}, \text{Kl}(\mathbb{R})) \rightarrow \text{Comod}(\mathbb{T}, \mathcal{C})$, whose value at \mathcal{S} is the tensor product $\mathcal{S} \cdot \mathcal{M}$. We can obtain $\mathcal{U} \cdot \mathcal{S}$ to the right similarly.

► **Remark 28.** While space precludes a full treatment here, we remark that the tensor product to the right of (11) allows us to re-find the *lazy composition* of intensional stream processors, described in [7, §4], as the unique map of \mathbb{T}_A -residual \mathbb{T}_C -comodels $\mathcal{I}_{BC} \cdot \mathcal{I}_{AB} \rightarrow \mathcal{I}_{AC}$

4 Extensional stream processors as a final bimodel

In Section 3, we characterised the set of intensional stream processors as a final \mathbb{T}_A -residual \mathbb{T}_B -comodel. In this section, we give the main result of the paper, characterising the set of extensional stream processors $Top(A^{\mathbb{N}}, B^{\mathbb{N}})$ as a final *bimodel* [4, 22, 3] for \mathbb{T}_A and \mathbb{T}_B .

► **Definition 29** (Bimodel). *Let \mathbb{T} and \mathbb{R} be theories. An \mathbb{R} - \mathbb{T} -bimodel \mathbf{K} is an \mathbb{R} -model $(\mathbf{K}, \llbracket - \rrbracket_{\mathbf{K}})$ endowed with \mathbb{T} -comodel structure $\llbracket - \rrbracket^{\mathbf{K}}$ in the category $Mod(\mathbb{R})$ of \mathbb{R} -models.*

The main difficulty in working with \mathbb{R} - \mathbb{T} -bimodels is handling copowers in $Mod(\mathbb{R})$. A simple case is that of *free* \mathbb{R} -models: a copower of free models is free, and so we have canonical isomorphisms $B \cdot \mathbf{R}(V) \cong \mathbf{R}(B \times V)$, which for convenience, we will assume are in fact *identities*, i.e., that the chosen copower $B \cdot \mathbf{R}(V)$ is $\mathbf{R}(B \times V)$. The \mathbb{R} - \mathbb{T} -bimodels with free underlying \mathbb{R} -model are easy to identify: they correspond precisely to \mathbb{R} -residual \mathbb{T} -comodels, where the \mathbb{R} - \mathbb{T} -bimodel $\mathbf{R}(\mathbf{S})$ corresponding to the \mathbb{R} -residual \mathbb{T} -comodel \mathbf{S} has underlying \mathbb{R} -model $\mathbf{R}(S)$ and co-operations $\llbracket \sigma \rrbracket^{\mathbf{R}(\mathbf{S})} = (\llbracket \sigma \rrbracket^{\mathbf{S}})^{\dagger} : \mathbf{R}(S) \rightarrow \mathbf{R}(|\sigma| \times S)$, where $(-)^{\dagger}$ is the Kleisli extension operation of Lemma 6.

To understand what we gain by looking at bimodels with non-free underlying model, it is helpful to think in terms of quotients by bisimulations. If \mathbf{S} is an \mathbb{R} -residual \mathbb{T} -comodel, then we could define (cf. [17, Definition 5.2]) a *bisimulation* on \mathbf{S} to be an equivalence relation \sim on S such that each co-operation $\llbracket \sigma \rrbracket^{\mathbf{S}}$ sends \sim -related states to \approx -related computations in $\mathbf{R}(|\sigma| \times S)$, where \approx is the congruence generated by $(i, s) \approx (i, s')$ whenever $s \sim s'$. The definition ensures that the residual comodel structure descends to the quotient set S/\sim ; however, this only gives the possibility of identifying operationally equivalent *states*, and not operationally equivalent *computations* over states. The following more generous definition rectifies this.

► **Definition 30** (\mathbb{R} -bisimulation). *Let \mathbb{R} and \mathbb{T} be theories. For any \mathbb{R} -congruence \sim on the free model $\mathbf{R}(V)$ and any set B , the congruence \sim_B on $\mathbf{R}(B \times V)$ is that generated by*

$$t \sim u \text{ in } \mathbf{R}(V) \quad \Longrightarrow \quad t(\lambda s.(b, s)) \sim_B u(\lambda s.(b, s)) \text{ for all } b \in B.$$

If \mathbf{S} is an \mathbb{R} -residual \mathbb{T} -comodel, then a congruence on $\mathbf{R}(S)$ is an \mathbb{R} -bisimulation if the co-operations $\llbracket \sigma \rrbracket^{\mathbf{R}(\mathbf{S})} = (\llbracket \sigma \rrbracket^{\mathbf{S}})^{\dagger} : \mathbf{R}(S) \rightarrow \mathbf{R}(|\sigma| \times S)$ of the associated bimodel send \sim -congruent terms to $\sim_{|\sigma|}$ -congruent terms.

► **Lemma 31.** *Let \mathbf{S} be an \mathbb{R} -residual \mathbb{T} -comodel and \sim an \mathbb{R} -bisimulation on $\mathbf{R}(S)$. There is a unique structure of \mathbb{R} - \mathbb{T} -bimodel on the quotient \mathbb{R} -model $\mathbf{K} = \mathbf{R}(S)/\sim$ for which the the quotient map $q : \mathbf{R}(S) \rightarrow \mathbf{K}$ becomes a map of bimodels $\mathbf{R}(\mathbf{S}) \rightarrow \mathbf{K}$.*

Proof. If $\mathbf{R}(S)/\sim = \mathbf{K}$ then $\mathbf{R}(B \times S)/\sim_B$ is a presentation of the copower $B \cdot \mathbf{K}$. So the assumption that \sim is an \mathbb{R} -bisimulation ensures that each basic co-operation of $\mathbf{R}(\mathbf{S})$ descends to a co-operation on \mathbf{K} , as to the left in:

$$\begin{array}{ccc} \mathbf{R}(S) \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{R}(\mathbf{S})}} \mathbf{R}(|\sigma| \times S) & & \mathbf{R}(S) \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{R}(\mathbf{S})}} \mathbf{R}(V \times S) \\ q \downarrow & \Downarrow q_{|\sigma|} & q \downarrow & \Downarrow q_V \\ \mathbf{K} \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{K}}} \rightarrow |\sigma| \cdot \mathbf{K} & & \mathbf{K} \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{K}}} \rightarrow V \cdot \mathbf{K} \end{array}$$

Since $\mathbf{R}(|\sigma| \times S)$ is the copower $|\sigma| \cdot \mathbf{R}(S)$, and the quotient map $q_{|\sigma|}$ is the copower $|\sigma| \cdot q$, it follows that the *derived* co-operations of $\mathbf{R}(\mathbf{S})$ descend to the corresponding *derived* co-operations on \mathbf{K} , as to the right above; whence the satisfaction of the \mathbb{T} -comodel equations for $\mathbf{R}(\mathbf{S})$ implies the corresponding satisfaction for \mathbf{K} . So \mathbf{K} is an \mathbb{R} - \mathbb{T} -bimodel, and clearly this is the *unique* bimodel structure making q into a bimodel homomorphism. ◀

We can use this construction to explain how the passage from the final \mathbb{T}_A -residual \mathbb{T}_B -comodel to the final \mathbb{T}_A - \mathbb{T}_B -bimodel will collapse the intensionality we saw in Example 22.

► **Example 32.** Consider the two \mathbb{T}_A -residual \mathbb{T}_B -comodels \mathbf{S}_1 and \mathbf{S}_2 of Example 22. While there is clearly no scope for quotienting by a bisimulation on the set of states $\{*\}$, we *can* non-trivially quotient each by a \mathbb{T}_A -bisimulation on $\mathbf{T}_A(*)$: namely the \mathbb{T}_A -congruence on $\mathbf{T}_A(*)$ generated by $* \sim \text{read}(\lambda a. *)$. It is easy to see that this is a \mathbb{T}_A -bisimulation for both \mathbf{S}_1 and \mathbf{S}_2 , and so we obtain quotient \mathbb{T}_A - \mathbb{T}_B -bimodels $\mathbf{T}_A(\mathbf{S}_1)/\sim$ and $\mathbf{T}_A(\mathbf{S}_2)/\sim$. In fact, these are visibly the *same* bimodel \mathbf{K} , with underlying \mathbb{T}_A -model the final model $\{*\}$, and with \mathbb{T}_B -comodel structure $\llbracket \text{read} \rrbracket^{\mathbf{K}} : \mathbf{K} \rightarrow B \cdot \mathbf{K}$ given by the b th coproduct injection. So we have a cospan of bimodels $\mathbf{T}_A(\mathbf{S}_1) \rightarrow \mathbf{K} \leftarrow \mathbf{T}_A(\mathbf{S}_2)$, which in particular implies that the states $*$ of $\mathbf{T}_A(\mathbf{S}_1)$ and $\mathbf{T}_A(\mathbf{S}_2)$ must be identified in a *final* \mathbb{T}_A - \mathbb{T}_B -bimodel.

This example provides supporting evidence for the main theorem we shall now prove: that the set $\text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}})$ of extensional stream processors is a final \mathbb{T}_A - \mathbb{T}_B -bimodel. To show this, we will first construct an adjunction as to the left in

$$\text{Mod}(\mathbb{T}_A) \xleftarrow[\text{(-)} \otimes A^{\mathbb{N}}]{\text{Top}(A^{\mathbb{N}}, -)} \text{Top} \quad \text{Comod}(\mathbb{T}_B, \text{Mod}(\mathbb{T}_A)) \xleftarrow[\text{(-)} \otimes A^{\mathbb{N}}]{\text{Top}(A^{\mathbb{N}}, -)} \text{Comod}(\mathbb{T}_B, \text{Top}) \quad (12)$$

We then show that *both* directions of this adjunction preserve coproducts, so in particular copowers; it will then follow that the adjunction to the left lifts to one as to the right on \mathbb{T}_B -comodels. The right adjoint of this lifted adjunction, like any right adjoint, will preserve terminal objects, and so must send the final topological \mathbb{T}_B -comodel $\mathbf{B}^{\mathbb{N}}$ to a final \mathbb{T}_A - \mathbb{T}_B -bimodel, with underlying set $\text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}})$.

To construct the adjunction to the left in (12) we apply a standard result of category-theoretic universal algebra (cf. [4, Theorem 2]). For self-containedness we give a full proof.

► **Proposition 33.** *Let \mathcal{C} be a category with copowers and \mathbf{S} a \mathbb{T} -comodel in \mathcal{C} . For any object $C \in \mathcal{C}$, the hom-set $\mathcal{C}(\mathbf{S}, C)$ bears a structure of \mathbb{T} -model $\mathcal{C}(\mathbf{S}, C)$ with operations*

$$\llbracket \sigma \rrbracket_{\mathcal{C}(\mathbf{S}, C)} (\lambda i. S \xrightarrow{f_i} C) = S \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{S}}} |\sigma| \cdot S \xrightarrow{\langle f_i \rangle_{i \in |\sigma|}} C \quad (13)$$

where $\langle f_i \rangle_{i \in |\sigma|}$ is the copairing of the f_i 's. As C varies, this assignment underlies a functor $\mathcal{C}(\mathbf{S}, -) : \mathcal{C} \rightarrow \text{Mod}(\mathbb{T})$. If \mathcal{C} is cocomplete, this functor has a left adjoint $(-) \otimes \mathbf{S} : \text{Mod}(\mathbb{T}) \rightarrow \mathcal{C}$.

Proof. For any $C \in \mathcal{C}$, the hom-functor $\mathcal{C}(-, C) : \mathcal{C}^{\text{op}} \rightarrow \text{Set}$ sends copowers in \mathcal{C} to powers in Set , and so sends \mathbb{T} -comodels in \mathcal{C} to \mathbb{T} -models in Set . In particular, the \mathbb{T} -model induced by $\mathbf{S} \in \text{Comod}(\mathbb{T}, \mathcal{C})$ is $\mathcal{C}(\mathbf{S}, C)$ with the operations defined above. The functoriality of this assignment is clear, so it remains to exhibit the desired adjoint when \mathcal{C} is cocomplete.

To this end, note that a \mathbb{T} -model homomorphism $\alpha : \mathbf{X} \rightarrow \mathcal{C}(\mathbf{S}, C)$ is equally a function $\alpha : X \rightarrow \mathcal{C}(\mathbf{S}, C)$ such that, for all basic \mathbb{T} -operations σ and all $\vec{x} \in X^{|\sigma|}$, we have

$$S \xrightarrow{\alpha(\llbracket \sigma \rrbracket_{\mathbf{X}}(\vec{x}))} C = S \xrightarrow{\llbracket \sigma \rrbracket^{\mathbf{S}}} |\sigma| \cdot S \xrightarrow{\langle \alpha(x_i) \rangle_{i \in |\sigma|}} C.$$

Transposing under $(-) \cdot S \dashv \mathcal{C}(\mathbf{S}, -) : \mathcal{C} \rightarrow \text{Set}$, this is equally to give a map $\bar{\alpha} : X \cdot S \rightarrow C$ in \mathcal{C} such that, for each basic \mathbb{T} -operation σ , postcomposition with $\bar{\alpha}$ equalises the two maps

$$X^{|\sigma|} \cdot S \xrightarrow{\llbracket \sigma \rrbracket_{\mathbf{X}} \cdot C} X \cdot S \quad X^{|\sigma|} \cdot S \xrightarrow{X^{|\sigma|} \cdot \llbracket \sigma \rrbracket^{\mathbf{X}}} X^{|\sigma|} \cdot (|\sigma| \cdot S) \cong (X^{|\sigma|} \times |\sigma|) \cdot S \xrightarrow{\text{ev} \cdot S} X \cdot S.$$

Thus, defining $\mathbf{X} \otimes \mathbf{S}$ to be the joint coequaliser of these parallel pairs as σ varies across the basic \mathbb{T} -operations, we have bijections $\mathcal{C}(\mathbf{X} \otimes \mathbf{S}, C) \cong \text{Mod}(\mathbb{T})(\mathbf{X}, \mathcal{C}(\mathbf{S}, C))$ natural in $C \in \mathcal{C}$, so that $\mathbf{X} \otimes \mathbf{S}$ is the value at \mathbf{X} of the desired left adjoint $(-) \otimes \mathbf{S}$. ◀

15:12 Stream Processors and Comodels

► **Remark 34.** Again, the final part of this result expresses an abstract fact: $Mod(\mathbb{T})$ is the free cocomplete category containing a comodel of \mathbb{T} .

In particular, we may apply the preceding result when \mathcal{C} is the cocomplete category Top and \mathbf{S} is the final topological \mathbb{T}_A -comodel $\mathbf{A}^{\mathbb{N}}$ to obtain an adjunction as to the left in (12). We now show that both directions of this adjunction preserve coproducts, and so in particular copowers. Since left adjoints always preserve colimits, there is only work to do for the right adjoint $Top(\mathbf{A}^{\mathbb{N}}, -): Top \rightarrow Mod(\mathbb{T}_A)$. First we spell out that, on objects, this functor acts by taking a space C to the set of continuous functions $Top(\mathbf{A}^{\mathbb{N}}, C)$, under the A -ary magma structure split that takes a family $(f_a : a \in A)$ of functions to the function $\mathit{split}(\vec{f})$ with

$$\mathit{split}(\vec{f})(\vec{a}) = f_{a_0}(\partial\vec{a}). \quad (14)$$

In other words, $\mathit{split}(\vec{f})$ consumes the first token a_0 of its input and then continues as f_{a_0} on the rest of its input; note that split is in fact invertible, with inverse given by the function $\mathit{split}^{-1}(f) = (f(a_-) : a \in A)$. This describes the action of $Top(\mathbf{A}^{\mathbb{N}}, -): Top \rightarrow Mod(\mathbb{T}_A)$ on objects; on morphisms, it simply acts by postcomposition.

The following result is the main piece of serious work needed to complete our result; it refines the topological arguments described in [7, Theorem 2.1], and used there to construct the reification function for intensional stream processors.

► **Proposition 35.** *The functor $Top(\mathbf{A}^{\mathbb{N}}, -): Top \rightarrow Mod(\mathbb{T}_A)$ preserves coproducts.*

Proof. Given spaces $(X_i : i \in I)$, we have the coproduct injections $\iota_i: X_i \rightarrow \Sigma_i X_i$ in Top , and must show that the family of postcomposition maps

$$(\iota_i \circ (-): Top(\mathbf{A}^{\mathbb{N}}, X_i) \rightarrow Top(\mathbf{A}^{\mathbb{N}}, \Sigma_i X_i))_{i \in I} \quad (15)$$

constitute a coproduct cocone in $Mod(\mathbb{T}_A)$. We first show:

► **Lemma 36.** *The maps (15) are jointly epimorphic in $Mod(\mathbb{T}_A)$.*

Proof. We show that the sub- A -ary magma $M \subseteq Top(\mathbf{A}^{\mathbb{N}}, \Sigma_i X_i)$ generated by the image of the maps (15) is all of $Top(\mathbf{A}^{\mathbb{N}}, \Sigma_i X_i)$. So suppose not; then there exists some continuous $f: \mathbf{A}^{\mathbb{N}} \rightarrow \Sigma_i X_i$ with $f \notin M$. Since we have $f = \mathit{split}(\mathit{split}^{-1}(f)) = \mathit{split}(\lambda a. f(a_-))$, we can find $a_0 \in A$ with $f(a_0-) \notin M$. Now repeating the argument with $f(a_0-)$, we can find $a_1 \in A$ with $f(a_0 a_1-) \notin M$; and continuing in this fashion, making countably many dependent choices, we find some $\vec{a} \in \mathbf{A}^{\mathbb{N}}$ such that for all n , the continuous function $f(a_0 a_1 \dots a_n -): \mathbf{A}^{\mathbb{N}} \rightarrow \Sigma_i X_i$ is not in M . In particular, none of these functions factor through any X_i ; but as $f(\vec{a}) \in X_i$ for some i , this means there is *no* open neighbourhood of \vec{a} which is mapped by f into the open neighbourhood X_i of $f(\vec{a})$, contradicting the continuity of f . ◀

Thus, to complete the proof, we need only show that, for a cocone $(p_i: Top(\mathbf{A}^{\mathbb{N}}, X_i) \rightarrow \mathbf{Y})_{i \in I}$ in $Mod(\mathbb{T}_A)$, there exists *some* map $p: Top(\mathbf{A}^{\mathbb{N}}, \Sigma_i X_i) \rightarrow \mathbf{Y}$ with $p \circ Top(\mathbf{A}^{\mathbb{N}}, \iota_i) = p_i$ for each i . To this end, consider the diagram of A -ary magmas

$$\begin{array}{ccc} & \mathbf{N} & \\ \varepsilon \swarrow & & \searrow \tilde{p} \\ Top(\mathbf{A}^{\mathbb{N}}, \Sigma_i X_i) & \xrightarrow{p} & \mathbf{Y} \end{array}$$

where $\mathbf{N} = (N, \nu)$ is the free A -ary magma generated by symbols $[f, i]$ for $i \in I$ and $f \in Top(\mathbf{A}^{\mathbb{N}}, X_i)$, where ε sends $[f, i]$ to $\iota_i f$ and where \tilde{p} sends $[f, i]$ to $p_i(f)$. It suffices to exhibit a factorisation p of \tilde{p} through ε as displayed. Now by the lemma above, ε is

epimorphic, and so the coequaliser of its kernel-congruence; so to obtain such a factorisation, it suffices to show that if $x, y \in N$ satisfy $\varepsilon(x) = \varepsilon(y)$, then they satisfy $\tilde{p}(x) = \tilde{p}(y)$. We do so by induction on the total number of magma operations ν in x and y :

- If $x = [f, i]$ and $y = [g, j]$ then $\varepsilon(x) = \varepsilon(y)$ says that $\iota_i f = \iota_j g$, which is possible only if $i = j$ and $f = g$. So $x = y$ and so certainly $\tilde{p}(x) = \tilde{p}(y)$.
- If $x = [f, i]$ and $y = \nu(\lambda a. y_a)$ then on taking $x_a = [f(a-), i]$ for each a , we get from $\varepsilon(x) = \varepsilon(y)$ that

$$\text{split}(\lambda a. \varepsilon(x_a)) = \text{split}(\lambda a. \iota_i f(a-)) = \iota_i f = \varepsilon(x) = \varepsilon(y) = \varepsilon(\nu(\lambda a. y_a)) = \text{split}(\lambda a. \varepsilon(y_a))$$

which, since split is invertible, implies that $\varepsilon(x_a) = \varepsilon(y_a)$ for each $a \in A$. By induction, we have $\tilde{p}(x_a) = \tilde{p}(y_a)$ for each a , and so we have the desired equality:

$$\tilde{p}(x) = p_i(f) = \text{split}(\lambda a. p_i(f(a-))) = \text{split}(\lambda a. \tilde{p}(x_a)) = \text{split}(\lambda a. \tilde{p}(y_a)) = \tilde{p}(\nu(\lambda a. y_a)) = \tilde{p}(y).$$

- The case where $x = \nu(\lambda a. x_a)$ and $y = [g, j]$ is dual.
- Finally, if $x = \nu(\lambda a. x_a)$ and $y = \nu(\lambda a. y_a)$, then from $\varepsilon(x) = \varepsilon(y)$ we get

$$\text{split}(\lambda a. \varepsilon(x_a)) = \varepsilon(\nu(\lambda a. x_a)) = \varepsilon(x) = \varepsilon(y) = \varepsilon(\nu(\lambda a. y_a)) = \text{split}(\lambda a. \varepsilon(y_a))$$

and so by invertibility of split that $\varepsilon(x_a) = \varepsilon(y_a)$ for all a . By induction, $\tilde{p}(x_a) = \tilde{p}(y_a)$ for all a , and so the desired equality

$$\tilde{p}(x) = \tilde{p}(\nu(\lambda a. x_a)) = \text{split}(\lambda a. \tilde{p}(x_a)) = \text{split}(\lambda a. \tilde{p}(y_a)) = \tilde{p}(\nu(\lambda a. y_a)) = \tilde{p}(y). \quad \blacktriangleleft$$

Using this result, we can conclude the argument as explained above. Since both adjoints to the left of (12) preserve coproducts, the adjunction lifts to an adjunction between categories of \mathbb{T}_B -comodels as to the right. In particular, the lifted right adjoint sends the final topological \mathbb{T}_B -comodel to a final \mathbb{T}_A - \mathbb{T}_B -bimodel, so giving our main theorem:

► **Theorem 37.** *For any sets A and B , the final \mathbb{T}_A - \mathbb{T}_B -bimodel \mathbf{E}_{AB} is given by the set of continuous functions $\text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}})$ with the \mathbb{T}_A -model structure of (14), and with the \mathbb{T}_B -comodel structure map*

$$\text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}}) \xrightarrow{(g, n) \circ (-)} \text{Top}(A^{\mathbb{N}}, B \cdot B^{\mathbb{N}}) \xrightarrow{\cong} B \cdot \text{Top}(A^{\mathbb{N}}, B^{\mathbb{N}}), \quad (16)$$

whose first part is postcomposition with (1) and whose second part is the canonical isomorphism coming from the fact that $\text{Top}(A^{\mathbb{N}}, -): \text{Top} \rightarrow \text{Mod}(\mathbb{T}_A)$ preserves coproducts.

We now describe (16) more concretely, but first we describe copowers in $\text{Mod}(\mathbb{T}_A)$.

► **Lemma 38.** *For any \mathbb{T}_A -model $\mathbf{X} = (X, \xi)$ and set B , the copower $B \cdot \mathbf{X}$ may be found as either: (i) the quotient of $\mathbf{T}_A(B \times X)$ by the congruence which identifies*

$$\begin{array}{c} (b, x_a) \quad \cdots \quad (b, x_{a'}) \\ \diagdown \quad \quad \quad \diagup \\ \bullet \\ | \end{array} \quad \sim \quad (b, \xi(\lambda a. x_a)); \quad (17)$$

or: (ii) the subset of $\mathbf{T}_A(B \times X)$ on those A -ary branching trees where no non-trivial subtree has all its leaves labelled by the same element of B , with the \mathbb{T}_A -model structure map v being that of $\mathbf{T}_A(B \times X)$ except that $v(\lambda a. (b, x_a)) = (b, \xi(\lambda a. x_a))$.

Proof. (i) is the presentation $\mathbf{T}_A(B \times X)/\sim_B$ from Lemma 31 when \sim is the congruence associated to the quotient $\text{id}^\dagger: \mathbf{T}_A(X) \rightarrow \mathbf{X}$. As for (ii), these elements are the normal forms for the strongly normalising rewrite system obtained by applying (17) from left to right. ◀

Via presentation (i), we may thus describe (16) by associating to each $f \in \text{Top}(A^\mathbb{N}, B^\mathbb{N})$ a suitable tree in $T_A(B \times \text{Top}(A^\mathbb{N}, B^\mathbb{N}))$. For this, we use the identification of $B^\mathbb{N}$ with $B \cdot B^\mathbb{N}$ via $\vec{b} \mapsto (b_0, \partial \vec{b})$, together with Lemma 36, to see that f lies in the closure under the A -ary magma operation **split** on $\text{Top}(A^\mathbb{N}, B^\mathbb{N})$ of the set of those $g: A^\mathbb{N} \rightarrow B^\mathbb{N}$ for which $g(\vec{a})_0$ is constant. (This expresses algebraically the fact that, for each $\vec{a} \in A^\mathbb{N}$, there is some finite initial segment $a_0 \dots a_k$ of \vec{a} such that $f(\vec{a}')_0 = f(\vec{a})_0$ whenever $a_0 \dots a_k = a'_0 \dots a'_k$.)

Choosing any such presentation of f gives a well-founded A -ary tree (encoding the applications of **split**) with leaves labelled by functions $g: A^\mathbb{N} \rightarrow B^\mathbb{N}$ with $g(\vec{a})_0$ constant. Each such g is equally specified by the constant $b = g(\vec{a})_0$, and the function $h = \partial \circ g: A^\mathbb{N} \rightarrow B^\mathbb{N}$, so that our leaf labels are equally elements in $B \times \text{Top}(A^\mathbb{N}, B^\mathbb{N})$: so altogether we have an element of $T_A(B \times \text{Top}(A^\mathbb{N}, B^\mathbb{N}))$. Note that choosing a different presentation of f would yield a different element of $T_A(B \times \text{Top}(A^\mathbb{N}, B^\mathbb{N}))$; however, our theory ensures that these elements are congruent under (17), so yielding a well-defined element of $B \cdot \text{Top}(A^\mathbb{N}, B^\mathbb{N})$.

5 Comparing intensional and extensional stream processors

To conclude the paper, we examine the unique maps from an arbitrary $\mathbb{T}_A\text{-}\mathbb{T}_B$ -bimodel to the final one, showing that these act as expected via the extent function of Definition 17; and, finally, we give a comodel-theoretic explanation of the reflection-reification pair $I_{AB} \leftarrow E_{AB}$.

We begin with a small refinement of Proposition 33.

► **Proposition 39** (cf. [20, Theorem 4.4]). *Let \mathcal{C} be a cocomplete category and \mathbf{S} a \mathbb{T} -comodel in \mathcal{C} . The functor $(-) \otimes \mathbf{S}$ of Proposition 33 may be chosen to render commutative the following diagram, whose top edge is as in (9), and whose left edge is as in Definition 7:*

$$\begin{array}{ccc} \text{Kl}(\mathbb{T}) & \xrightarrow{(-) \cdot \mathbf{S}} & \mathcal{C} \\ I_{\mathbb{T}} \downarrow & \nearrow & \\ \text{Mod}(\mathbb{T}) & & (-) \otimes \mathbf{S} \end{array} \quad (18)$$

Proof. For a free \mathbb{T} -model $\mathbf{T}(V)$, we have natural bijections $\text{Mod}(\mathbb{T})(\mathbf{T}(V), \mathcal{C}(\mathbf{S}, C)) \cong \text{Set}(V, \mathcal{C}(\mathbf{S}, C)) \cong \mathcal{C}(V \cdot \mathbf{S}, C)$, and so we may take $\mathbf{T}(V) \otimes \mathbf{S} = V \cdot \mathbf{S}$. This makes (18) commute on objects. On morphisms, given $\theta^\dagger: \mathbf{T}(V) \rightarrow \mathbf{T}(W)$ in $\text{Mod}(\mathbb{T})$, its image $\theta^\dagger \otimes \mathbf{S}: V \cdot \mathbf{S} \rightarrow W \cdot \mathbf{S}$ under $(-) \otimes \mathbf{S}$ is, by adjointness, the unique map making:

$$\begin{array}{ccccc} \mathcal{C}(W \cdot \mathbf{S}, C) & \xrightarrow{\cong} & \text{Set}(W, \mathcal{C}(\mathbf{S}, C)) & \xrightarrow{\cong} & \text{Mod}(\mathbb{T})(\mathbf{T}W, \mathcal{C}(\mathbf{S}, C)) \\ (-) \circ (\theta^\dagger \otimes \mathbf{S}) \downarrow & & \downarrow \text{dotted} & & \downarrow (-) \circ \theta^\dagger \\ \mathcal{C}(V \cdot \mathbf{S}, C) & \xrightarrow{\cong} & \text{Set}(V, \mathcal{C}(\mathbf{S}, C)) & \xrightarrow{\cong} & \text{Mod}(\mathbb{T})(\mathbf{T}V, \mathcal{C}(\mathbf{S}, C)) \end{array}$$

commute for all $C \in \mathcal{C}$. Now, the unique dotted map making the right square commute is, by the freeness of $\mathbf{T}(V)$, the function

$$(f_w \in \mathcal{C}(\mathbf{S}, C) : w \in W) \quad \mapsto \quad ([\theta(v)]_{\mathcal{C}(\mathbf{S}, C)}(\vec{f}) : v \in V) .$$

But by induction on (13), we have $[\theta(v)]_{\mathcal{C}(\mathbf{S}, C)}(\vec{f}) = S \xrightarrow{[\theta(v)]^{\mathbf{S}}} W \cdot S \xrightarrow{\langle f_i \rangle_{i \in |\sigma|}} C$; whence we must have $\theta^\dagger \otimes \mathbf{S} = \langle [\theta(v)]^{\mathbf{S}} \rangle_{v \in V} = \theta \cdot \mathbf{S}$ as desired. ◀

We now characterise the unique maps to \mathbf{E}_{AB} from bimodels induced by residual comodels.

► **Proposition 40.** *Let \mathbf{S} be a \mathbb{T}_A -residual \mathbb{T}_B -comodel. The unique bimodel map from the associated bimodel $f: \mathbf{T}_A(\mathbf{S}) \rightarrow \mathbf{E}_{AB}$ is $(\lambda s.e(s, -))^\dagger$, the homomorphic extension of the currying $S \rightarrow \text{Top}(A^\mathbb{N}, B^\mathbb{N})$ of the extent function of Definition 17.*

Proof. Since $(-) \otimes \mathbf{A}^\mathbb{N}: \text{Mod}(\mathbb{T}_A) \rightarrow \text{Top}$ restricts back along $I_{\mathbb{T}_A}$ to $(-) \cdot \mathbf{A}^\mathbb{N}: \text{Kl}(\mathbb{T}_A) \rightarrow \text{Top}$, its lifting to a functor on \mathbb{T}_B -comodels must, by Remark 27, restrict along $I_{\mathbb{T}_A}$ to the tensor product of Definition 26. So the unique \mathbb{T}_B -comodel map $\mathbf{T}_A(\mathbf{S}) \otimes \mathbf{A}^\mathbb{N} \rightarrow \mathbf{B}^\mathbb{N}$ must be the extent map $\mathbf{S} \cdot \mathbf{A}^\mathbb{N} \rightarrow \mathbf{B}^\mathbb{N}$ of Definition 17. By the proof of Proposition 39, transposing this to a bimodel map $\mathbf{T}_A(\mathbf{S}) \rightarrow \mathbf{E}_{AB}$ is achieved by currying and extending homomorphically. ◀

We now do the same for the unique maps to \mathbf{E}_{AB} from *arbitrary* \mathbb{T}_A - \mathbb{T}_B -bimodels. To do so, we show that every such bimodel arises in a canonical way from the construction of Lemma 31. Note that this is *not* true for arbitrary theories \mathbb{R} and \mathbb{T} .

► **Lemma 41.** *Let \mathbf{K} be a \mathbb{T}_A - \mathbb{T}_B -bimodel. The composite*

$$\gamma = K \xrightarrow{[\text{read}]^\mathbf{K}} B \cdot K \xrightarrow{\subseteq} T_A(B \times K)$$

where we take $B \cdot \mathbf{K} \subseteq T_A(B \times K)$ as in Lemma 38(ii), endows K with the structure of a \mathbb{T}_A -residual \mathbb{T}_B -comodel $\check{\mathbf{K}}$. The congruence on $\mathbf{T}_A(K)$ generating the \mathbb{T}_A -model quotient map $\text{id}_K^\dagger: \mathbf{T}_A(K) \twoheadrightarrow \mathbf{K}$ is a \mathbb{T}_A -bisimulation for $\check{\mathbf{K}}$ and the quotient bimodel is precisely \mathbf{K} .

Proof. Only the final sentence requires any verification; it will follow if we can show that the square of \mathbb{T}_A -model maps to the left below is commutative:

$$\begin{array}{ccc} \mathbf{T}_A(K) & \xrightarrow{\gamma^\dagger} & \mathbf{T}_A(B \times K) \\ \text{id}_K^\dagger \downarrow & & \downarrow B \cdot \text{id}_K^\dagger \\ \mathbf{K} & \xrightarrow{[\text{read}]^\mathbf{K}} & B \cdot \mathbf{K} \end{array} \qquad \begin{array}{ccc} K & \xrightarrow{[\text{read}]^\mathbf{K}} & B \cdot K \xrightarrow{\iota} T_A(B \times K) \\ \text{id} \downarrow & & \downarrow B \cdot \text{id}_K^\dagger \\ K & \xrightarrow{[\text{read}]^\mathbf{K}} & B \cdot K \end{array}$$

which by freeness will happen just when the diagram to the right also commutes. But the map $B \cdot \text{id}_K^\dagger$ therein is the quotient map by the congruence of (17), of which ι must be a section since it selects a family of equivalence-class representatives. ◀

If \mathbf{K} is a bimodel, then $\check{\mathbf{K}}$ is the *maximally lazy* realisation of \mathbf{K} as a residual comodel, wherein the program associated to each state $k \in \mathbf{K}$ reads the absolute minimum number of input A -tokens required to determine the next output B -token, with all subsequent reading from A handed off (via the \mathbb{T}_A -model structure on \mathbf{K}) to the continuation state.

► **Proposition 42.** *Let \mathbf{K} be a \mathbb{T}_A - \mathbb{T}_B -bimodel. The image of $k \in \mathbf{K}$ under the unique bimodel map $\mathbf{K} \rightarrow \mathbf{E}_{AB}$ is the continuous function $e(k, -): A^\mathbb{N} \rightarrow B^\mathbb{N}$, where e is the topological extent function associated to the \mathbb{T}_A -residual \mathbb{T}_B -comodel $\check{\mathbf{K}}$ of Lemma 41.*

Proof. By Lemma 41 we have a quotient map of bimodels $\text{id}_K^\dagger: \mathbf{T}_A(\check{\mathbf{K}}) \twoheadrightarrow \mathbf{K}$ which of necessity fits into a commuting triangle

$$\begin{array}{ccc} \mathbf{T}_A(\check{\mathbf{K}}) & \xrightarrow{\text{id}_K^\dagger} & \mathbf{K} \\ \downarrow ! & & \downarrow ! \\ & \mathbf{E}_{AB} & \end{array}$$

The left edge of this triangle is the map identified in the preceding proposition. Thus, tracing elements $k \in K \subseteq T_A(K)$ around the two sides of this triangle yields the result. ◀

Finally, we give use the above results to give a comodel-theoretic reconstruction of the reflection-reification pair. We already defined $\text{reflect}: I_{AB} \rightarrow E_{AB}$ in Definition 21. In the other direction, we define the *reification function* $\text{reify}: E_{AB} \rightarrow I_{AB}$ as the underlying map of the unique residual comodel map $\check{E}_{AB} \rightarrow I_{AB}$.

► **Proposition 43.** *We have $\text{reflect} \circ \text{reify} = \text{id}_{E_{AB}}$.*

Proof. By Proposition 40, the unique \mathbb{T}_A - \mathbb{T}_B -bimodel map $T_A(I_{AB}) \rightarrow E_{AB}$ is reflect^\dagger , while by Lemma 41, $\text{id}_{E_{AB}}^\dagger$ is the unique bimodel \mathbb{T}_A - \mathbb{T}_B -bimodel map $T_A(\check{E}_{AB}) \rightarrow E_{AB}$. So we have a (necessarily commuting) triangle of \mathbb{T}_A - \mathbb{T}_B -bimodel maps:

$$\begin{array}{ccc} T_A(\check{E}_{AB}) & \xrightarrow{T_A(\text{reify})} & T_A(I_{AB}) \\ & \searrow \text{id}_{E_{AB}}^\dagger & \swarrow \text{reflect}^\dagger \\ & E_{AB} & \end{array}$$

and precomposing with $\eta: E_{AB} \rightarrow T_A(E_{AB})$ yields the result. ◀

As the notation suggests, the composite $\text{reify} \circ \text{reflect}$ implements *normalisation-by-evaluation* for intensional stream processors, where the normal forms are the maximally lazy elements of I_{AB} . For instance, the trees $t_1, t_2 \in I_{AB}$ of Example 22 will both normalise to t_1 .
