Abstract. Modal dependence logic was introduced very recently by Väänänen. It enhances the basic modal language by an operator dep . For propositional variables p_1, \dots, p_n , $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ intuitively states that the value of p_n only depends on those of p_1, \dots, p_{n-1} . Sevenster (J. Logic and Computation, 2009) showed that satisfiability for modal dependence logic is complete for nondeterministic exponential time.

In this paper we consider fragments of modal dependence logic obtained by restricting the set of allowed propositional connectives. We show that satisfiability for *poor man's dependence logic*, the language consisting of formulas built from literals and dependence atoms using \wedge , \Box , \Diamond (i.e., disallowing disjunction), remains NEXPTIME-complete. If we only allow monotone formulas (without negation, but with disjunction), the complexity drops to PSPACE-completeness. We also extend Väänänen's language by allowing classical disjunction besides dependence disjunction and show that the satisfiability problem remains NEXPTIME-complete. If we then disallow both negation and dependence disjunction, satisfiability is complete for the second level of the polynomial hierarchy.

In this way we completely classify the computational complexity of the satisfiability problem for all restrictions of propositional and dependence operators considered by Väänänen and Sevenster.

Keywords: dependence logic, satisfiability problem, computational complexity, poor man's logic

1 Introduction

In his recent monograph [14], Jouko Väänänen introduced functional dependence into the language of first-order logic. Dependence among values of variables occurs everywhere in computer science (databases, software engineering, knowledge representation, AI) but also the social sciences (human history, stock markets, etc.), and thus dependence logic is nowadays a much discussed formalism in the area called *logic for interaction*.

Functional dependence of the value of a variable p_n from the values of the variables p_1, \dots, p_{n-1} states that there is a function, say f , such that $p_n =$

$f(p_1, \dots, p_{n-1})$, i. e., the value of p_n only depends on those of p_1, \dots, p_{n-1} . We will denote this in this paper by $\text{dep}(p_1, \dots, p_{n-1}; p_n)$.

Of course, dependence does not manifest itself in a single world, play, event or observation. Important for such a dependence to make sense is a collection of such worlds, plays, events or observations. These collections are called *teams*. They are the basic objects in the definition of semantics of dependence logic. A team can be a set of plays in a game. Then $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ intuitively states that in each play, move p_n is determined by moves p_1, \dots, p_{n-1} . A team can be a database. Then $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ intuitively states that in each line, the value of attribute p_n is determined by the values of attributes p_1, \dots, p_{n-1} , i. e., that p_n is functionally dependent on p_1, \dots, p_{n-1} . In first-order logic, a team formally is a set of assignments; and $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ states that in each assignment, the value of p_n is determined by the values of p_1, \dots, p_{n-1} . Most important for this paper, in modal logic, a team is a set of worlds in a Kripke structure; and $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ states that in each of these worlds, the value of the propositional variable p_n is determined by the values of p_1, \dots, p_{n-1} .

Dependence logic is defined by simply adding these dependence atoms to usual first-order logic [14]. Modal dependence logic (MDL) is defined by introducing these dependence atoms to modal logic [15,13]. The semantics of MDL is defined with respect to sets T of worlds in a frame (Kripke structure) W , for example $W, T \models \text{dep}(p_1, \dots, p_{n-1}; p_n)$ if for all worlds $s, t \in T$, if p_1, \dots, p_{n-1} have the same values in both s and t , then p_n has the same value in s and t , and a formula

$$\Box \text{dep}(p_1, \dots, p_{n-1}; p_n)$$

is satisfied in a world w in a Kripke structure W , if in the team T consisting of all successor worlds of w , $W, T \models \text{dep}(p_1, \dots, p_{n-1}; p_n)$.

MDL was introduced in [15]. Väänänen introduced besides the usual inductive semantics an equivalent game-theoretic semantics. Sevenster [13] considered the expressibility of MDL and proved, that on singleton teams T , there is a translation from MDL to usual modal logic, while on arbitrary sets of teams there is no such translation. Sevenster also initiated a complexity-theoretic study of modal dependence logic by proving that the satisfiability problem for MDL is complete for the class NEXPTIME of all problems decidable nondeterministically in exponential time.

In this paper, we continue the work of Sevenster by presenting a more thorough study on complexity questions related to modal dependence logic. A line of research going back to Lewis [9] and recently taken up in a number of papers [12,5,3,10] has considered fragments of different propositional logics by restricting the propositional and temporal operators allowed in the language. The rationale behind this approach is that by systematically restricting the language, one might find a fragment with efficient algorithms but still high enough expressibility in order to be interesting for applications. This in turn might lead to better tools for model checking, verification, etc. On the other hand, it is worthwhile to identify the sources of hardness: What exactly makes satisfiability, model checking, or other problems so hard for certain languages?

We follow the same approach here. We consider all subsets of modal operators \Box, \Diamond and propositional operators \wedge, \vee, \neg (atomic negation), \top, \perp (the Boolean constants true and false), i. e., we study exactly those operators considered by Väänänen [15], and examine the satisfiability problem for MDL restricted to the fragment given by these operators. In each case we exactly determine the computational complexity in terms of completeness for a complexity class such as NEXPTIME, PSPACE, coNP, etc., or by showing that the satisfiability problem admits an efficient (polynomial-time) solution. We also extend the logical language of [15] by adding classical disjunction (denoted here by \bigvee) besides the dependence disjunction. Connective \bigvee was already considered by Sevenster (he denoted it by \bullet), but not from a complexity point of view. In this way, we obtain a complexity analysis of the satisfiability problem for MDL for all subsets of operators studied by Väänänen and Sevenster.

Our results are summarized in Table 1, where $+$ denotes presence and $-$ denotes absence of an operator, and $*$ states that the complexity does not depend on the operator. One of our main and technically most involved contributions addresses a fragment that has been called *Poor Man's Logic* in the literature on modal logic [5], i. e., the language without disjunction \vee . We show that for dependence logic we still have full complexity (Theorem 5, first line of the table), i. e., we show that Poor Man's Dependence Logic is NEXPTIME-complete. If we also forbid negation, then the complexity drops down to $\Sigma_2^P (= \text{NP}^{\text{NP}})$; i. e., Monotone Poor Man's Dependence Logic is Σ_2^P -complete (Theorem 4, 5th line, but note that we need \bigvee here).

2 Modal Dependence Logic

We will only briefly introduce the syntax and semantics of modal dependence logic here. For a more profound overview consult Väänänen's introduction [15] or Sevenster's analysis [13] which includes a self-contained introduction to MDL.

2.1 Syntax

The formulas of *modal dependence logic* (MDL) are built from a set AP of *atomic propositions* and the MDL operators $\Box, \Diamond, \wedge, \vee, \neg$ (also denoted \neg), \top, \perp , dep and \bigvee

The set of MDL *formulas* is defined by the following grammar

$$\varphi ::= \top \mid \perp \mid p \mid \neg p \mid \text{dep}(p_1, \dots, p_{n-1}; p_n) \mid \neg\text{dep}(p_1, \dots, p_{n-1}; p_n) \mid \\ \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \varphi \bigvee \varphi \mid \Box \varphi \mid \Diamond \varphi,$$

where $n \geq 1$.

All formulas in the first row will sometimes be denoted as *atomic* formulas and formulas of the form $\text{dep}(p_1, \dots, p_{n-1}; p_n)$ as *dependence atoms*. We sometimes write ∇^k for $\underbrace{\nabla \dots \nabla}_{k \text{ times}}$ (with $\nabla \in \{\Box, \Diamond\}$, $k \in \mathbb{N}$).

All results are completeness results except for the P cases.

2.2 Semantics

A *frame* (or *Kripke structure*) is a tuple $W = (S, R, \pi)$ where S is a non-empty set of *worlds*, $R \subseteq S \times S$ is the *accessibility relation* and $\pi : S \rightarrow \mathcal{P}(AP)$ is the *labeling function*.

In contrast to usual modal logic, truth of a MDL formula is not defined with respect to a single world of a frame but with respect to a set of worlds, as already pointed out in the introduction. The *truth* of a MDL formula φ in an *evaluation set* T of worlds of a frame $W = (S, R, \pi)$ is denoted by $W, T \models \varphi$ and is defined as follows:

$W, T \models p$	iff	$p \in \pi(s)$ for all $s \in T$
$W, T \models \neg p$	iff	$p \notin \pi(s)$ for all $s \in T$
$W, T \models \text{dep}(p_1, \dots, p_{n-1}; p_n)$	iff	for all $s_1, s_2 \in T$ with $\pi(s_1) \cap \{p_1, \dots, p_{n-1}\} = \pi(s_2) \cap \{p_1, \dots, p_{n-1}\} :$ $p_n \in \pi(s_1)$ iff $p_n \in \pi(s_2)$
$W, T \models \neg \text{dep}(p_1, \dots, p_{n-1}; p_n)$	iff	$T = \emptyset$
$W, T \models \varphi \wedge \psi$	iff	$W, T \models \varphi$ and $W, T \models \psi$
$W, T \models \varphi \vee \psi$	iff	there are sets T_1, T_2 with $T = T_1 \cup T_2$, $W, T_1 \models \varphi$ and $W, T_2 \models \psi$
$W, T \models \varphi \bigcirc \psi$	iff	$W, T \models \varphi$ or $W, T \models \psi$
$W, T \models \Box \varphi$	iff	$W, \{s' \mid \exists s \in T \text{ with } (s, s') \in R\} \models \varphi$

$W, T \models \diamond\varphi$ iff there is a set $T' \subseteq S$ such that $W, T' \models \varphi$ and
for all $s \in T$ there is a $s' \in T'$ with $(s, s') \in R$

By \vee we denote dependence disjunction instead of classical disjunction because the semantics of dependence disjunction is an extension of the semantics of usual modal logic disjunction and thus we preserve downward compatibility of our notation in this way. Note that rationales for the seemingly rather strange definitions of the truth of $\varphi \vee \psi$ as well as $\neg\text{dep}(p_1, \dots, p_{n-1}; p_n)$ were given by Väänänen [15,14].

For each $M \subseteq \{\Box, \diamond, \wedge, \vee, \bar{\cdot}, \top, \perp, \text{dep}, \bigcirc\}$ define the set of $\text{MDL}(M)$ formulas to be the set of MDL formulas which are built from atomic propositions using only operators and constants from M .

We are interested in the parameterized decision problem **MDL-SAT(M)**:

Given: A $\text{MDL}(M)$ formula φ .

Question: Is there a frame W and a set T of worlds in W such that $W, T \models \varphi$?

Note that, as Väänänen already pointed out [15, Lemma 4.2.1], the semantics of MDL satisfies the *downward closure property*, i.e., if $W, T \models \varphi$, then $W, T' \models \varphi$ for all $T' \subseteq T$. Hence, to check satisfiability of a formula φ it is enough to check whether there is a frame W and a single world w in W such that $W, \{w\} \models \varphi$.

3 Complexity Results

To state the first lemma we need the following complexity operator. If \mathcal{C} is an arbitrary complexity class then $\exists \cdot \mathcal{C}$ denotes the class of all sets A for which there is a set $B \in \mathcal{C}$ and a polynomial p such that for all x ,

$$x \in A \text{ iff there is a } y \text{ with } |y| \leq p(|x|) \text{ and } \langle x, y \rangle \in B.$$

Our first lemma concerns sets of operators including classical disjunction.

Lemma 1. *Let M be a set of MDL operators. Then it holds:*

- a) *Every $\text{MDL}(M \cup \{\bigcirc\})$ formula φ is equivalent to a formula $\bigcirc_{i=1}^{2^{|\varphi|}} \psi_i$ with $\psi_i \in \text{MDL}(M)$ for all $i \in \{1, \dots, 2^{|\varphi|}\}$.*
- b) *If \mathcal{C} is an arbitrary complexity class with $\text{P} \subseteq \mathcal{C}$ and $\text{MDL-SAT}(M) \in \mathcal{C}$ then $\text{MDL-SAT}(M \cup \{\bigcirc\}) \in \exists \cdot \mathcal{C}$.*

Proof. a) follows from the distributivity of \bigcirc with all other operators. More specifically $\varphi \star (\psi \bigcirc \sigma) \equiv (\varphi \star \psi) \bigcirc (\varphi \star \sigma)$ for $\star \in \{\wedge, \vee\}$ and $\nabla(\varphi \bigcirc \psi) \equiv (\nabla\varphi) \bigcirc (\nabla\psi)$ for $\nabla \in \{\diamond, \Box\}$.¹ b) follows from a) with the observation that $\bigcirc_{i=1}^{2^{|\varphi|}} \psi_i$ is satisfiable if and only if there is an $i \in \{1, \dots, 2^{|\varphi|}\}$ such that ψ_i is satisfiable. \square

We need the following simple property of monotone MDL formulas.

¹ Interestingly, but not of relevance for our work, $\varphi \bigcirc (\psi \vee \sigma) \not\equiv (\varphi \bigcirc \psi) \vee (\varphi \bigcirc \sigma)$.

Lemma 2. *Let M be a set of MDL operators with $\bar{\top} \notin M$. Then an arbitrary MDL(M) formula φ is satisfiable iff the formula generated from φ by replacing every dependence atom and every atomic proposition with \top is satisfiable.*

Proof. If a frame W is a model for φ , so is the frame generated from W by setting all atomic propositions in all worlds to \top . \square

We are now able to classify some cases that can be easily reduced to known results.

- Corollary 3.** *a) If $\{\Box, \Diamond, \wedge, \vee, \bar{\top}\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \bar{\top}, \top, \perp, \bigcirc\}$ then MDL-SAT(M) is PSPACE-complete.*
b) If $\{\Box, \Diamond, \wedge, \vee, \perp\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \top, \perp, \text{dep}, \bigcirc\}$ then MDL-SAT(M) is PSPACE-complete.
c) If $\{\Box, \Diamond, \wedge, \perp\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \top, \perp, \text{dep}\}$ then MDL-SAT(M) is coNP-complete.
d) If $M \subseteq \{\Box, \Diamond, \wedge, \vee, \top, \text{dep}, \bigcirc\}$ then every MDL(M) formula is satisfiable.

Proof. a) follows immediately from Ladner’s proof for the case of ordinary modal logic [8], Lemma 1 and $\exists \cdot \text{PSPACE} = \text{PSPACE}$. The lower bound for b) was shown by Hemaspaandra [5, Theorem 6.5] and the upper bound follows from a) together with Lemma 2. The lower bound for c) was shown by Donini et al. [4] and the upper bound follows from Ladner’s algorithm [8] together with Lemma 2. d) follows from Lemma 2 together with the fact that every MDL formula with \top as the only atomic subformula is satisfied in every transitive singleton, i.e. the frame consisting of only one state which has itself as successor. \square

3.1 Poor Man’s Dependence Logic

We now turn to the Σ_2^P -complete cases. These include monotone poor man’s logic, with and without dependence atoms.

Theorem 4. *If $\{\Box, \Diamond, \wedge, \bar{\top}, \bigcirc\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \bar{\top}, \top, \perp, \bigcirc\}$ or $\{\Box, \Diamond, \wedge, \perp, \bigcirc\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \top, \perp, \text{dep}, \bigcirc\}$ then MDL-SAT(M) is Σ_2^P -complete.*

Proof. Proving the upper bound for the second case reduces to proving the upper bound for the first case by Lemma 2. For the first case it holds with Lemma 1 that $\text{MDL-SAT}(\Box, \Diamond, \wedge, \bar{\top}, \top, \perp, \bigcirc) \in \exists \cdot \text{coNP} = \Sigma_2^P$ since $\text{MDL-SAT}(\Box, \Diamond, \wedge, \bar{\top}, \top, \perp) \in \text{coNP}$, which follows directly from Ladner’s AP-algorithm for modal logic satisfiability [8].

For the lower bound we consider the quantified constraint satisfaction problem $\text{QCSP}_2(\mathbb{R}_{1/3})$ shown to be Π_2^P -complete by Bauland et al. [2]. This problem can be reduced to the complement of $\text{MDL-SAT}(\Box, \Diamond, \wedge, \bar{\top}/\perp, \bigcirc)$ in polynomial time.

An instance of $\text{QCSP}_2(\mathbb{R}_{1/3})$ consists of universally quantified Boolean variables p_1, \dots, p_k , existentially quantified Boolean variables p_{k+1}, \dots, p_n and a set of clauses each consisting of exactly three of those variables. $\text{QCSP}_2(\mathbb{R}_{1/3})$ is

the set of all those instances for which for every truth assignment for p_1, \dots, p_k there is a truth assignment for p_{k+1}, \dots, p_n such that in each clause exactly one variable evaluates to true.²

For the reduction from $\text{QCSP}_2(\mathbb{R}_{1/3})$ to the complement of $\text{MDL-SAT}(\Box, \Diamond, \wedge, \neg/\perp, \bigcirc)$ we extend a technique from the coNP-hardness proof for $\text{MDL-SAT}(\Box, \Diamond, \wedge, \perp)$ by Donini et al. [4, Theorem 3.3]. Let p_1, \dots, p_k be the universally quantified and p_{k+1}, \dots, p_n the existentially quantified variables of a $\text{QCSP}_2(\mathbb{R}_{1/3})$ instance and let C_1, \dots, C_m be its clauses (we assume w.l.o.g. that each variable occurs in at least one clause). Then the corresponding $\text{MDL}(\Box, \Diamond, \wedge, \perp, \bigcirc)$ formula is

$$\begin{aligned} \varphi := & \bigwedge_{i=1}^k \left(\begin{array}{ccc} \nabla_{i1} \dots \nabla_{im} \nabla_{i1} \dots \nabla_{im} \Box^{i-1} \Diamond \Box^{k-i} p & & \\ \bigcirc \Box^m & \Box^m & \Box^{i-1} \Diamond \Box^{k-i} p \end{array} \right) \\ & \wedge \bigwedge_{i=k+1}^n \begin{array}{ccc} \nabla_{i1} \dots \nabla_{im} \nabla_{i1} \dots \nabla_{im} \Box^k & & p \end{array} \\ & \wedge \begin{array}{ccc} \Box^m & \Box^m & \Box^k \quad \perp \end{array} \end{aligned}$$

where p is an arbitrary atomic proposition and $\nabla_{ij} := \begin{cases} \Diamond & \text{if } p_i \in C_j \\ \Box & \text{else} \end{cases}$.

For the corresponding $\text{MDL}(\Box, \Diamond, \wedge, \neg, \bigcirc)$ formula replace every \perp with $\neg p$.

To prove the correctness of our reduction we will need two claims.

Claim 1. For $r, s \geq 0$ a $\text{MDL}(\Box, \Diamond, \wedge, \neg, \top, \perp)$ formula $\Diamond \varphi_1 \wedge \dots \wedge \Diamond \varphi_r \wedge \Box \psi_1 \wedge \dots \wedge \Box \psi_s$ is unsatisfiable iff there is an $i \in \{1, \dots, r\}$ such that $\varphi_i \wedge \psi_1 \wedge \dots \wedge \psi_s$ is unsatisfiable.

Proof of Claim 1. “ \Leftarrow ”: If $\varphi_i \wedge \psi_1 \wedge \dots \wedge \psi_s$ is unsatisfiable, so is $\Diamond \varphi_i \wedge \Box \psi_1 \wedge \dots \wedge \Box \psi_s$ and even more $\Diamond \varphi_1 \wedge \dots \wedge \Diamond \varphi_r \wedge \Box \psi_1 \wedge \dots \wedge \Box \psi_s$.

“ \Rightarrow ”: Suppose that $\varphi_i \wedge \psi_1 \wedge \dots \wedge \psi_s$ is satisfiable for all $i \in \{1, \dots, r\}$. Then $\Diamond \varphi_1 \wedge \dots \wedge \Diamond \varphi_r \wedge \Box \psi_1 \wedge \dots \wedge \Box \psi_s$ is satisfiable in a frame that consists of a root state and for each $i \in \{1, \dots, r\}$ a separate branch, reachable from the root in one step, which satisfies $\varphi_i \wedge \psi_1 \wedge \dots \wedge \psi_s$. \llcorner

Note that $\Diamond \varphi_1 \wedge \dots \wedge \Diamond \varphi_r \wedge \Box \psi_1 \wedge \dots \wedge \Box \psi_s$ is always satisfiable if $r = 0$.

Definition. Let $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$ be a valuation of $\{p_1, \dots, p_k\}$. Then φ_v denotes the $\text{MDL}(\Box, \Diamond, \wedge, \neg/\perp)$ formula

$$\begin{aligned} & \bigwedge_{\substack{i \in \{1, \dots, k\}, \\ v(p_i)=1}} \begin{array}{ccc} \nabla_{i1} \dots \nabla_{im} \nabla_{i1} \dots \nabla_{im} \Box^{i-1} \Diamond \Box^{k-i} p & & \\ \Box^m & \Box^m & \Box^{i-1} \Diamond \Box^{k-i} p \end{array} \\ \wedge & \bigwedge_{\substack{i \in \{1, \dots, k\}, \\ v(p_i)=0}} \begin{array}{ccc} \Box^m & \Box^m & \Box^{i-1} \Diamond \Box^{k-i} p \end{array} \\ \wedge & \bigwedge_{i=k+1}^n \begin{array}{ccc} \nabla_{i1} \dots \nabla_{im} \nabla_{i1} \dots \nabla_{im} \Box^k & & p \end{array} \\ \wedge & \begin{array}{ccc} \Box^m & \Box^m & \Box^k \quad \neg p / \perp \end{array} \end{aligned}$$

² For our reduction it is necessary that in each clause the variables are pairwise different whereas in $\text{QCSP}_2(\mathbb{R}_{1/3})$ this need not be the case. However, the Π_2^P -hardness proof can easily be adapted to account for this (see Lemma 8 in the Appendix).

Claim 2. Let $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$ be a valuation. Then φ_v is unsatisfiable iff v can be continued to a valuation $v' : \{p_1, \dots, p_n\} \rightarrow \{0, 1\}$ such that in each of the clauses $\{C_1, \dots, C_m\}$ exactly one variable evaluates to true under v' .

Proof of Claim 2. By iterated use of Claim 1, φ_v is unsatisfiable iff there are i_1, \dots, i_{2m} with

$$\begin{aligned} i_j \in & \{i \in \{1, \dots, n\} \mid \nabla_{ij'} = \diamond\} \setminus \{i \in \{1, \dots, k\} \mid v(p_i) = 0\} \\ = & \{i \in \{1, \dots, n\} \mid p_i \in C_{j'}\} \setminus \{i \in \{1, \dots, k\} \mid v(p_i) = 0\}, \end{aligned}$$

where $j' := \begin{cases} j & \text{if } j \leq m \\ j - m & \text{else} \end{cases}$, such that

$$\begin{aligned} \varphi_v(i_1, \dots, i_{2m}) := & \bigwedge_{\substack{i \in \{1, \dots, k\}, \\ i \in \{i_1, \dots, i_{2m}\}, \\ v(p_i) = 1}} \square^{i-1} \diamond \square^{k-i} p \\ & \wedge \bigwedge_{\substack{i \in \{1, \dots, k\}, \\ v(p_i) = 0}} \square^{i-1} \diamond \square^{k-i} p \\ & \wedge \bigwedge_{\substack{i \in \{k+1, \dots, n\}, \\ i \in \{i_1, \dots, i_{2m}\}}} \square^k p \\ & \wedge \square^k \neg p / \perp \end{aligned}$$

is unsatisfiable (*i*) and such that there are no $a, b \in \{1, \dots, 2m\}$ with $a < b$, $\nabla_{i_b a'} = \nabla_{i_b b'} = \diamond$ (this is the case iff $p_{i_b} \in C_{a'}$ and $p_{i_b} \in C_{b'}$) and $i_a \neq i_b$ (*ii*). The latter condition is already implied by Claim 1 as it simply ensures that no subformula is selected after it has already been discarded in an earlier step. Note that $\varphi_v(i_1, \dots, i_{2m})$ is unsatisfiable iff for all $i \in \{1, \dots, k\}$: $v(p_i) = 1$ and $i \in \{i_1, \dots, i_{2m}\}$ or $v(p_i) = 0$ (and $i \notin \{i_1, \dots, i_{2m}\}$) (*i'*).

We are now able to prove the claim.

“ \Leftarrow ”: For $j = 1, \dots, 2m$ choose $i_j \in \{1, \dots, n\}$ such that $p_{i_j} \in C_{j'}$ and $v'(p_{i_j}) = 1$. By assumption, all i_j exist and are uniquely determined. Hence, for all $i \in \{1, \dots, k\}$ we have that $v(p_i) = 0$ (and then $i \notin \{i_1, \dots, i_{2m}\}$) or $v(p_i) = 1$ and there is a j such that $i_j = i$ (because each variable occurs in at least one clause). Therefore condition (*i'*) is satisfied. Now suppose there are $a < b$ that violate condition (*ii*). By definition of i_b it holds that $p_{i_b} \in C_{b'}$ and $v'(p_{i_b}) = 1$. Analogously, $p_{i_a} \in C_{a'}$ and $v'(p_{i_a}) = 1$. By the supposition $p_{i_b} \in C_{a'}$ and $p_{i_a} \neq p_{i_b}$. But since $v'(p_{i_a}) = v'(p_{i_b}) = 1$, that is a contradiction to the fact that in clause $C_{a'}$ only one variable evaluates to true.

“ \Rightarrow ”: If φ_v is unsatisfiable, there are i_1, \dots, i_{2m} such that (*i'*) and (*ii*) hold. Let the valuation $v' : \{p_1, \dots, p_n\} \rightarrow \{0, 1\}$ be defined by

$$v'(p_i) := \begin{cases} 1 & \text{if } i \in \{i_1, \dots, i_{2m}\} \\ 0 & \text{else} \end{cases}.$$

Note that v' is a continuation of v because (*i'*) holds.

We will now prove that in each of the clauses C_1, \dots, C_m exactly one variable evaluates to true under v' . Therefore let $j \in \{1, \dots, m\}$ be arbitrarily chosen.

By choice of i_j it holds that $p_{i_j} \in C_j$. It follows by definition of v' that $v'(p_{i_j}) = 1$. Hence, there is at least one variable in C_j that evaluates to true.

Now suppose that besides p_{i_j} another variable in C_j evaluates to true. Then by definition of v' it follows that there is a $\ell \in \{1, \dots, 2m\}$, $\ell \neq j$, such that this other variable is p_{i_ℓ} . We now consider two cases.

Case $j < \ell$: This is a contradiction to (ii) since, by definition of ℓ , p_{i_ℓ} is in $C_{j'}$ as well as, by definition of i_ℓ , in $C_{\ell'}$ and $i_j \neq i_\ell$.

Case $\ell < j$: Since $j \in \{1, \dots, m\}$ it follows that $\ell \leq m$. Since $C_{\ell'} = C_{(\ell+m)'}$ it holds that $p_{i_{\ell+m}} \in C_{\ell'}$ and $p_{i_{\ell+m}} \in C_{(\ell+m)'}$. Furthermore $\ell < \ell + m$ and thus, by condition (ii), it must hold that $i_\ell = i_{\ell+m}$. Therefore $p_{i_{\ell+m}} \in C_j$ and $v'(p_{i_{\ell+m}}) = 1$. Because $j < \ell + m$ this is a contradiction to condition (ii) as in the first case. <<

The correctness of the reduction now follows with the observation that φ is equivalent to $\bigvee_{v: \{p_1, \dots, p_k\} \rightarrow \{0,1\}} \varphi_v$ and that φ is unsatisfiable iff φ_v is unsatisfiable

for all valuations $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$.

The QCSP₂(R_{1/3}) instance is true iff every valuation $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$ can be continued to a valuation $v' : \{p_1, \dots, p_n\} \rightarrow \{0, 1\}$ such that in each of the clauses $\{C_1, \dots, C_m\}$ exactly one variable evaluates to true under v' iff, by Claim 2, φ_v is unsatisfiable for all $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$ iff, by the above observation, φ is unsatisfiable. □

Next we turn to (non-monotone) poor man's logic.

Theorem 5. *If $\{\square, \diamond, \wedge, \neg, \text{dep}\} \subseteq M$ then MDL-SAT(M) is NEXPTIME-complete.*

Proof. Sevenster showed that the problem is in NEXPTIME in the case of $\bigvee \notin M$ [13, Lemma 14]. Together with Lemma 1 and the fact that $\exists \cdot \text{NEXPTIME} = \text{NEXPTIME}$ the upper bound applies.

For the lower bound we reduce 3CNF-DQBF, which was shown to be NEXPTIME-hard by Peterson et al. [11, Lemma 5.2.2]³, to our problem.

An instance of 3CNF-DQBF consists of universally quantified Boolean variables p_1, \dots, p_k , existentially quantified Boolean variables p_{k+1}, \dots, p_n , dependence constraints $P_{k+1}, \dots, P_n \subseteq \{p_1, \dots, p_k\}$ and a set of clauses each consisting of three (not necessarily distinct) literals. Here, P_i intuitively states that the value of p_i only depends on the values of the variables in P_i . Now, 3CNF-DQBF is the set of all those instances for which there is a collection of functions f_{k+1}, \dots, f_n with $f_i : \{0, 1\}^{P_i} \rightarrow \{0, 1\}$ such that for every valuation $v : \{p_1, \dots, p_k\} \rightarrow \{0, 1\}$ there is at least one literal in each clause that evaluates to true under the valuation $v' : \{p_1, \dots, p_n\} \rightarrow \{0, 1\}$ defined by

$$v'(p_i) := \begin{cases} v(p_i) & \text{if } i \in \{1, \dots, k\} \\ f_i(v \upharpoonright P_i) & \text{if } i \in \{k+1, \dots, n\} \end{cases} .$$

³ Peterson et al. showed NEXPTIME-hardness for DQBF without the restriction that the formulae must be in 3CNF. However, the restriction does not lower the complexity since every propositional formula is satisfiability-equivalent to a formula in 3CNF whose size is bounded by a polynomial in the size of the original formula.

The functions f_{k+1}, \dots, f_n act as restricted existential quantifiers, i.e., for an $i \in \{k+1, \dots, n\}$ the variable p_i can be assumed to be existentially quantified dependent on all universally quantified variables in P_i (and, more importantly, independent of all universally quantified variables not in P_i). Dependencies are thus explicitly specified through the dependence constraints and can contain – but are not limited to – the traditional sequential dependencies, e.g. the quantifier sequence $\forall p_1 \exists p_2 \forall p_3 \exists p_4$ can be modeled by the dependence constraints $P_2 = \{p_1\}$ and $P_4 = \{p_1, p_3\}$.

For the reduction from 3CNF-DQBF to MDL-SAT($\Box, \Diamond, \wedge, \bar{\cdot}, \text{dep}$) we use an idea from the PSPACE-hardness proof of MDL-SAT($\Box, \Diamond, \wedge, \bar{\cdot}$) over a restricted frame class by Hemaspaandra [5, Theorem 4.2]. Let p_1, \dots, p_k be the universally quantified and p_{k+1}, \dots, p_n the existentially quantified variables of a 3CNF-DQBF instance φ and let P_{k+1}, \dots, P_n be its dependence constraints and $\{l_{11}, l_{12}, l_{13}\}, \dots, \{l_{m1}, l_{m2}, l_{m3}\}$ its clauses. Then the corresponding MDL($\Box, \Diamond, \wedge, \bar{\cdot}, \text{dep}$) formula is

$$\begin{aligned}
g(\varphi) := & \bigwedge_{i=1}^n \Box^{i-1} (\Diamond \Box^{n-i} p_i \wedge \Diamond \Box^{n-i} \bar{p}_i) & (i) \\
& \wedge \bigwedge_{i=1}^m \Diamond^n (\bar{l}_{i1} \wedge \bar{l}_{i2} \wedge \bar{l}_{i3} \wedge f_i) & (ii) \\
& \wedge \bigwedge_{i=1}^m \Box^n \text{dep}(l'_{i1}, l'_{i2}, l'_{i3}; f_i) & (iii) \\
& \wedge \Box^k \Diamond^{n-k} (\bar{f}_1 \wedge \dots \wedge \bar{f}_m \wedge \bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)) & (iv)
\end{aligned}$$

where $p_1, \dots, p_n, f_1, \dots, f_m$ are atomic propositions and $l'_{ij} := \begin{cases} p & \text{if } l_{ij} = p \\ \bar{p} & \text{if } l_{ij} = \bar{p} \end{cases}$.

Now if φ is valid, consider the frame which consists of a complete binary tree with n levels (not counting the root) and where each of the 2^n possible labelings of the atomic propositions p_1, \dots, p_n occurs in exactly one leaf. Additionally, for each $i \in \{1, \dots, m\}$ f_i is labeled in exactly those leaves in which $l_{i1} \vee l_{i2} \vee l_{i3}$ is false. This frame obviously satisfies (i), (ii) and (iii). And since the modalities in (iv) model the quantors of φ , \bar{f}_i is true exactly in the leaves in which $l_{i1} \vee l_{i2} \vee l_{i3}$ is true and the dep atoms in (iv) model the dependence constraints of φ , (iv) is also true and therefore $g(\varphi)$ is satisfied in the root of the tree.

As an example see Fig. 1 for a frame satisfying $g(\varphi)$ if the first clause in φ is $\{\bar{p}_1, p_n\}$.

If, on the other hand, $g(\varphi)$ is satisfiable, let W be a frame and t a world in W such that $W, \{t\} \models g(\varphi)$. Now (i) enforces W to contain a complete binary tree T with root t such that each labeling of p_1, \dots, p_n occurs in a leaf of T .

We can further assume w.l.o.g. that W itself is a tree since in MDL different worlds with identical proposition labelings are indistinguishable and therefore every frame can simply be unwinded to become a tree. Since the modal depth of $g(\varphi)$ is n we can assume that the depth of W is at most n . And since (i) enforces that every path in W from t to a leaf has a length of at least n , all leaves of W lie at levels greater or equal to n . Altogether we can assume that W is a tree, that all its leaves lie at level n and that it has the same root as T . The only difference is that the degree of W may be greater than that of T .

Fig. 1. Frame satisfying $g(\varphi)$

But we can nonetheless assume that up to level k the degree of W is 2 (*). This is the case because if any world up to level $k - 1$ had more successors than the two lying in T , the additional successors could be omitted and (i), (ii), (iii) and (iv) would still be fulfilled. For (i), (ii) and (iii) this is clear and for (iv) it holds because (iv) begins with \square^k .

We will now show that, although T may be a proper subframe of W , T is already sufficient to fulfill $g(\varphi)$. From this the validity of φ will follow immediately.

Claim. $T, \{t\} \models g(\varphi)$.

Proof of Claim. We consider sets of leaves of W that satisfy $\overline{f_1} \wedge \cdots \wedge \overline{f_m} \wedge \bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$ and that can be reached from the set $\{t\}$ by the modality sequence $\square^k \diamond^{n-k}$. Let S be such a set and let S be chosen so that there is no other such set that contains less worlds outside of T than S does. Assume there is a $s \in S$ that does not lie in T .

Let $i \in \{1, \dots, m\}$ and let s' be the leaf in T that agrees with s on the labeling of p_1, \dots, p_n . Then, with $W, \{s\} \models \overline{f_i}$ and (iii), it follows that $W, \{s'\} \models \overline{f_i}$.

Let $S' := (S \setminus \{s\}) \cup \{s'\}$. Then it follows by the previous paragraph that $W, S' \models \overline{f_1} \wedge \cdots \wedge \overline{f_m}$. Since $W, S \models \bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$ and s' agrees with s on the propositions p_1, \dots, p_n it follows that $W, S' \models \bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$. Hence, S' satisfies $\overline{f_1} \wedge \cdots \wedge \overline{f_m} \wedge \bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$ and as it only differs from S by replacing s with s' it can be reached from $\{t\}$ by $\square^k \diamond^{n-k}$ because s and s' agree on p_1, \dots, p_k and, by (*), W does not differ from T up to level k . But this is a contradiction to the assumption since S' contains one world less than S outside of T . Thus, there is no $s \in S$ that does not lie in T and therefore (iv) is fulfilled in T . Since (i), (ii) and (iii) are obviously also fulfilled in T , it follows that $T, \{t\} \models g(\varphi)$. <<

(ii) ensures that for all $i \in \{1, \dots, m\}$ there is a leaf in W in which $\neg(l_{i1} \vee l_{i2} \vee l_{i3}) \wedge f_i$ is true. This leaf can lie outside of T . However, (iii) ensures that all leaves that agree on the labeling of l_{i1} , l_{i2} and l_{i3} also agree on the labeling of f_i . And since there is a leaf where $\neg(l_{i1} \vee l_{i2} \vee l_{i3}) \wedge f_i$ is true, it follows that in all leaves, in which $\neg(l_{i1} \vee l_{i2} \vee l_{i3})$ is true, f_i is true. Conversely, if $\overline{f_i}$ is true in an arbitrary leaf of W then so is $l_{i1} \vee l_{i2} \vee l_{i3}$ (**).

The modality sequence $\Box^k \Diamond^{n-k}$ models the quantors of φ and $\bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$ models its dependence constraints. And so there is a bijective correspondence between sets of worlds reachable in T by $\Box^k \Diamond^{n-k}$ from $\{t\}$ and that satisfy $\bigwedge_{i=k+1}^n \text{dep}(P_i; p_i)$ on the one hand and truth assignments to p_1, \dots, p_n generated by the quantors of φ and satisfying its dependence constraints on the other hand. Additionally, by (**) follows that $\overline{f_1} \wedge \dots \wedge \overline{f_m}$ implies $\bigwedge_{i=1}^m (l_{i1} \vee l_{i2} \vee l_{i3})$ and since $T, \{t\} \models g(\varphi)$, φ is valid. \square

3.2 Cases with Only One Modality

We finally examine formulas with only one modality.

Theorem 6. *Let $M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \perp, \bigcirc\}$ with $\Box \notin M$ or $\Diamond \notin M$. Then the following hold:*

- a) $\text{MDL-SAT}(M \cup \{\text{dep}\}) \leq_{\text{m}}^{\text{p}} \text{MDL-SAT}(M \cup \{\top, \perp\})$, i.e., adding the dep operator does not increase the complexity if we only have one modality.
- b) For every $\text{MDL}(M \cup \{\text{dep}\})$ formula φ it holds that \bigcirc is equivalent to \vee , i.e., φ is equivalent to every formula that is generated from φ by replacing some or all occurrences of \bigcirc by \vee and vice versa.

Proof. Every negation $\neg \text{dep}$ of a dependence atom is by definition always equivalent to \perp and can thus be replaced by the latter. For positive dep atoms and the \bigcirc operator we consider two cases.

Case $\Diamond \notin M$. If an arbitrary $\text{MDL}(\Box, \wedge, \vee, \neg, \top, \perp, \text{dep}, \bigcirc)$ formula φ is satisfiable then it is so in an intransitive singleton frame, i.e. a frame that only contains one world which does not have a successor, because there every subformula that begins with a \Box is automatically satisfied. In a singleton frame all dep atoms obviously hold and \bigcirc is equivalent to \vee . Therefore the (un-)satisfiability of φ is preserved when substituting every dep atom in φ with \top and every \bigcirc with \vee (or vice versa).

Case $\Box \notin M$. If an arbitrary $\text{MDL}(\Diamond, \wedge, \vee, \neg, \top, \perp, \text{dep}, \bigcirc)$ formula φ is satisfiable then, by the downward closure property, there is a frame W with a world s such that $W, \{s\} \models \varphi$. Since there is no \Box in φ , every subformula of φ is also evaluated in a singleton set (because a \Diamond can never increase the cardinality of the evaluation set). And as in the former case we can replace every dep atom with \top and every \bigcirc with \vee (or vice versa). \square

Thus we obtain the following consequences – note that with the preceding results this takes care of all cases in Table 1.

Corollary 7. *a) If $\{\wedge, \neg\} \subseteq M \subseteq \{\Box, \Diamond, \wedge, \vee, \neg, \top, \perp, \text{dep}, \bigcirc\}$, $M \cap \{\vee, \bigcirc\} \neq \emptyset$ and $|M \cap \{\Box, \Diamond\}| = 1$ then MDL-SAT(M) is NP-complete.*

Proof. a) follows from [5, Theorem 6.2(2)] and Theorem 6a,b. b) follows from [5, Theorem 6.4(c,d)] and Theorem 6a. c) follows from [5, Theorem 6.4(e,f)] and Theorem 6a,b.

For d) the proof of [5, Theorem 6.4(b)] can be adapted as follows. Let φ be an arbitrary MDL(M) formula. By the same argument as in the proof of Theorem 6b we can replace all top-level (i.e. not lying inside a modality) occurrences of \bigcirc in φ with \vee to get the equivalent formula φ' . φ' is of the form $\Box\psi_1 \vee \dots \vee \Box\psi_k \vee \Diamond\sigma_1 \vee \dots \vee \Diamond\sigma_m \vee a_1 \vee \dots \vee a_s$ where every ψ_i and σ_i is a MDL(M) formula and every a_i is an atomic formula. If $k > 0$ or any a_i is a literal, \top or a dependence atom then φ' is satisfiable. Otherwise it is satisfiable iff one of the σ_i is satisfiable and this can be checked recursively in polynomial time. \square

4 Conclusion

In this paper we completely classified the complexity of the satisfiability problem for modal dependence logic for all fragments of the language defined by restricting the modal and propositional operators to a subset of those considered by Väänänen and Sevenster. Interestingly, our results show a dichotomy for the dep operator; either the complexity jumps to NEXPTIME-completeness when introducing dep or it does not increase at all – and in the latter case the dep operator does not increase the expressiveness of the logic.

In a number of precursor papers, e.g., [9] on propositional logic or [3] on modal logic, not only subsets of the classical operators $\{\Box, \Diamond, \wedge, \vee, \neg\}$ were considered but also propositional connectives given by arbitrary Boolean functions. The main result of Lewis, e.g., can be succinctly summarized as follows: Propositional satisfiability is NP-complete if and only if in the input formulas the connective $\varphi \wedge \neg\psi$ is allowed (or can be “implemented” with the allowed connectives).

We consider it interesting to initiate such a more general study for modal dependence logic and determine the computational complexity of satisfiability if the allowed connectives are taken from a fixed class in Post’s lattice. Contrary to propositional or modal logic, however, the semantics of such generalized formulas is not clear a priori – for instance, how should exclusive-or be defined in dependence logic? Even for simple implication, there seem to be several reasonable definitions, cf. [1].

A further possibly interesting restriction of dependence logic might be to restrict the type of functional dependency. Right now, dependence just means that there is some function whatsoever that determines the value of a variable from the given values of certain other variables. Also here it might be interesting to restrict the function to be taken from a fixed class in Post’s lattice, e.g., to be monotone or self-dual.

Related is the more general problem of finding interesting fragments of modal dependence logic where adding the dep operator does not let the complexity of

satisfiability testing jump up to NEXPTIME but still increases the expressiveness of the logic.

Finally, it seems advisable to study the expressiveness of MDL further – especially of the classical disjunction \bigvee and other extensions, e. g., implication. Also, the relation between MDL and first-order dependence logic seems to be an interesting field as there is no canonical embedding of MDL into first-order dependence logic.

Appendix

Lemma 8. $\text{QCSP}_2(\mathbf{R}_{1/3})$ with pairwise different variables in each clause is Π_2^P -hard.

Proof. We give a reduction from $3\text{CNF-}\overline{\text{QBF}}_2$. The only differences between an instance of $\text{QCSP}_2(\mathbf{R}_{1/3})$ and an instance of $3\text{CNF-}\overline{\text{QBF}}_2$ are that in the latter a clause may contain negated variables, more than one literal that evaluates to true and the same variable more than once.

Our reduction works as follows. The quantification of all original variables stays unchanged. All newly introduced variables are existentially quantified. Our new set of clauses consists of the clauses

- i) $\{t, f, f'\}, \{t, f', f''\}, \{t, f'', f\}$, where t, f, f', f'' are new variables,
- ii) for each original variable x : $\{x, x', f\}$ and
- iii) for each original clause $\{x, y, z\}$: $\{f, \hat{x}, a\}, \{a', \hat{y}, b\}, \{b', \hat{z}, f\},$
 $\{a, a', a''\}, \{b, b', b''\},$

where a, a', a'', b, b', b'' are new variables and $\hat{u} := \begin{cases} p & \text{if } u = p \\ p' & \text{if } u = \neg p \end{cases}$.

(i) enforces the new variable f to evaluate to \perp and (ii) simulates negated variables. (iii) uses $\mathbf{R}_{1/3}$ -clauses to allow for more than one of the three literals x, y and z to be true by splitting one old clause in three new clauses. But at the same time it still ensures that at least one of them is true by making the new variables interdependent in such a way that at most two of them can be true.
